 Oriel, Wingfield manor, 90
 Owen Jones competition, lace curtain (Sidney Smith), 352
 Oxford: interior of large hall, examination schools, 720; new belfry, Christ ch., 720

PANELS: drawing-room, 144; from Amiens cath., 62, 326; in school of art buildings (A. Marshall's design), 248
 Paper, wall, decorations, 198, 326
 Paris: ch. of Julien le Pauvre, 272; Hertford hospital, 536
 Passerotti's St. George and the Dragon, 412
 Patera from ceiling, 690
 Perspective, 400, 431
 Pianoforte, a grand, 34
 Pier, Gothic, development of, 170
 Plans: Art Union premises, 224; asylum (royal Albert, Lancaster), 720; board schools (Hanover-st., N.), 444, (Simm's Cross, Widnes) 380; boat-house (Caius coll, Cambridge), 536; bridge (Underley-park), 506; buffets, 380; cathedral (new, Melbourne), 536; churches (Bath, St. Mary R.C.) 224, (Bedford-park, St. Michael and All Angels') 118, (Clapham, St. Peter) 144, (Holborn, St. John Evan.) 6, (Mold, St. John Evan.) 412, (Paris, St. Julien le Pauvre) 272, (Shipton, St. Mary) 300, (Stoke Newington, All SS.) 90, (Truro, St. Mary) 144, (Watlington, SS. Peter and Paul) 300; cloisters and chapter house (Old St. Paul's), 183; college

(Mayo, Ajmer), 198; cottages (group of three), 272; cottage villa (H. Clifford's design), 600; cross ventilation (hospital wards), 187; dairy cottage (Highfield), 144; hemsteads (S. Murray), 62, (T. Potter) 248; fountain (Chippenhams), 34; glaciarium (Southport), 90; hospitals (cottage), 506, (Hertford, Paris) 536, (Norwich) 660, (triangular) 519; house (for four societies—W. R. Lethaby), 352, (of charity, St. Raphael's, Bristol) 34; houses (Carlisle, Chelsea Embankment), 506, (Claverton, Stoke Bishop) 90, (country—J. Sedding's design) 630, (Didsbury) 690, (Dybdale, Wellington) 568, (Hampstead) 300, (Llanerch Panna, Ellesmere) 198, (Putney-heath) 118, (Surbition) 62, (Wandsworth) 660; infirmary, Holborn Union, Highgate, 272; inns, wayside, 170, 224; mansions (Alexandra, Victoria-st., S.W.), 34, (Chelsea Embankment) 720; manufactory and warehouse (clothing, Leeds), 62; monastery (Downside), 660; museum (Natural History, Kensington), 170; oratory (Brompton), 474; perspective, 400, 431; premises (Clarendon-buildings, Hastings), 630, (Coleshill-st., Birmingham) 474; public buildings (Handsworth), 412; school (chapel, village), 690, (of art and science—A. Marshall's) 248; schools (City of London—Davis and Emmanuel's), 651; schools (divinity, Cambridge) 606; screw scaffolding, 568; stoup, Lewanick, 677, 765; Sunday school buildings, 396; tavern (King's Head, Fenchurch-st.), 157; town hall (Loftus in Cleveland), 600, (R.A. designs—W. Scott) 6, (R. W. Gibson) 118; university (Edinburgh), 720; vaulting, Roman and Gothic, 170; ventilators (Boyle's air-pump), 720; vestry hall (Bromley, St. Leonard), 660; village club-house (designing club), 34; villas (Green-hill, Hampstead), 6, (Leicester) 326, (Regent's-park, south), 444, (semi-detached) 118, (Turham-green) 412
 Porch, Lincoln cath., 224
 Prato, church tower at, 606
 Premises: Art Union, Strand, 224, 248, 272, 380, 444; Birmingham, 474; Broad-st., 690; New Bond-st., 300, 568; Rood-lane, 690; Wood-st., 6
 Proportion in church architecture, 766
 Provincial town hall, R.A. designs (R. W. Gibson), 118, (W. Scott) 6
 Public: buildings, Handsworth, 412; fountain, Chippenhams, 34
 Putney-heath, house at, 118

RED Lion-sq., Holborn, St. John Evangelist's ch., 6
 Regent's-park, south villa, 444
 Re-modelling St. Mary's ch., Woolwich (E. F. C. Clarke's design), 630
 Rheims cath., plan of apse, 536
 Rood-lane, E.C., new premises, 690
 Roof: collar-beam, strains, 678; controversy, St. Alban's, 23
 Royal Academy prize drawings: entrance gateway, Somerset House (R. W. Gibson), 6, 300; provincial town hall designs (R. W. Gibson), 118, (W. Scott) 6
 Royal Albert asylum, Lancaster, 720

SAFE and scientific water-closet, 131
 Salisbury cath., carvings, 630, 690
 Sash-fastener, Edwards's, 630
 Scaffolding, screw, 568
 School: chapel, village, 690; of art and science buildings (A. Marshall's design), 248
 Schools: Canobridge Univ. (divinity), 506; City of London (Davis and Emmanuel's plan), 651; Oxford (examin.), 720; Sedbergh, 118; Sunday, 396. See also under Board Schools.
 Scientific and safe water-closet, 131
 Screw scaffolding, 568
 Seats, St. Michael's ch., Bedford-park, 90
 Sections: buffets, 380; cathedral (Melbourne), 630; churches (Bedford-park, St. Michael), 62, 90, 118; cottage, 272; dairy homesteads, 62, 248; drawing-room cabinet, 144; dry-point lines, 393; etched and engraved lines, 369; fountain (Chippenhams), 34; French casement, 134; hospital, cottage, 506; house (Eastbourne), 248; lead on beam, 430, 464; premises (Art Union), 224, 248, 272, (New Bond-st.) 568; roof (St. Alban's cathedral), 23; screw scaffolding, 568; villas (semi-detached), 118
 Sedbergh grammar school, 118
 Semi-detached villas, 118
 Seventeenth century house at Derby, 170
 Shipton Bellingier church, Hants, 300
 Shrewsbury, dairy cottage, Highfield, near, 144
 Simm's Cross board schools, Widnes, 380
 Singular stoup at Lewanick, 677, 765
 Sketching club, archi. museum, 62, 326, 630, 690
 Soane medallion design, house for four learned societies (W. R. Lethaby), 352
 Societies, house for four (W. R. Lethaby's Soane design), 352
 Somerset House, entrance gateway, 6, 300
 South: Kensington, Natural History Museum, 170; porch, Lincoln cathedral, 224; villa, Regent's-park, 444
 Southport glaciarium, 90
 Southwark R.C. cathedral, niche and gratings, 600
 Speenhamland, St. Mary's church, 600
 St.: Alban's cathedral (roof section), 23; Anne and Agnes (Aldersgate-st., E.C.), 198; Barnabas (Beckenham), 90, 224; George and the Dragon, by Passerotti, 412, (Boto'ph-lane) 198, (R.C. cathedral, Southwark—details) 600; Giovanni (Viterbo), 506; Gregory (monastery, Downside), 660; John Evan. (Mold), 412, (Red Lion-sq., Holborn), 6; Julien le Pauvre (Paris), 272; Mary (Bath, R.C.), 224, (Shipton Bellingier) 300, (Speenhamland) 600, (Truro—proposed enlargement) 144; Michael and All Angels (Bedford-park, 62, 90, 118; Paul (Manchester), 568; Pauls, Old (chapter house and cloisters), 183; Peter (Bournemouth), 720, (Clapham) 144; Peter and Paul (Watlington), 300; Raphael (house of charity, Bristol), 34
 Staircase and dining-room, Finchley-road, 144
 Stoke: Bishop (Claverton house), 90; Newington (All SS. church), 90
 Stoup at Lewanick, 677, 765
 Strand, Art Union premises, 224, 248, 272, 380, 444

Strains on collar-beam roof, 678
 Studio, mansion and, Chelsea, 720
 Sunday-school buildings, plans, 396
 Sunderland, National Provincial Bank, 170

TAVERN, King's Head, Fenchurch-st., 157
 Thirteenth century architecture, 596, 597
 Three cottages, group of, 272
 Tomb of Edward the Black Prince, Canterbury, 34
 Towers: Manchester (St. Paul's ch.), 508; Norman, Bury St. Edmund's, 444; Prato, 506; Viterbo (S. Giovanni), 506
 Town halls: Kingstown, 352; Loftus-in-Cleveland, 600; provincial, R.A. designs (R. W. Gibson), 118, (W. Scott) 6; Wakefield (council chamber), 720
 Trabecate construction, development of, 170
 Triangular hospital plan, 519
 Truro, J. P. St. Aubyn's design for enlarging St. Mary's ch., 144
 Turnham-green: ch. of St. Michael and All Angels, 62, 90, 118; detached villas, 412
 Turret of Christ ch., Lambeth, 720
 Two Italian towers, 506

UNDERLEY PARK, bridge over Lane, 506
 University: college, Bristol (Colman and Wilcox's designs), 326, 568; divinity schools, Cambridge, 506; Edinburgh, 720; Oxford (belfry at Christ ch.), 720, (examin. schools) 720

VENTILATION, cross, hospital ward's, 187
 Ventilator: and sash-fastener, Edwards's, 630; Boyle's air-pump, 720
 Vestry hall, Bromley St. Leonard, 660
 Victoria-st., Westminster, Alexandra mansions, 34
 Villages: club-house, 34; school chapel, 690
 Villas: Bedford-park, 412; cottage, 600; Greenhill, Hampstead, 6; Leicester, 326; Regent's-park (south), 444; semi-detached, 118
 Viterbo, tower of S. Giovanni, 506

WAKEFIELD town hall, council chamber, 720
 Wall-paper decorations, Jeffrey's, 198, 326
 Wandsworth, house at Nightingale-lane, 660
 Wards, cross ventilation for, 187
 Warehouses: Bartholomew-close, E.C., 536; Belfast, 224; Leeds (clothing), 62
 Water-closet, a safe and scientific, 131
 Watling-street, new premises, 690
 Wayside inn, club designs for, 170, 224
 Wellingtonborough, Dybdale House, 568
 Westminster Abbey, plan of apse, 536
 Widnes, board schools, Simm's Cross, 380
 Windsor and Eton Albert Institute, 352
 Wingfield manor, Derbyshire, 90
 Wood-street, E.C., new premises in, 6
 Woolwich, proposed remodelling St. Mary's ch. (E. F. C. Clarke's design), 630
 Wrought ironwork, late, 600, 613, 614, 616

THE BUILDING NEWS

AND ENGINEERING JOURNAL.

RETROSPECTIVE.

THE year 1878 has not been an uneventful one in the history of architecture. If its practical achievements in building have been few, the incidents bearing upon the future of the profession have by no means been unimportant. Foremost among the few auspicious events to be recorded is the opening and close of the great gathering of arts and manufactures in Paris, which shone in remarkable contrast to the unsettled and disturbed condition of industry at home. The conference of architects held in June last, though it scarcely fulfilled its original purposes, dealt with a few questions of constantly recurring interest; while the policy of the Institute seems slowly to be undergoing a change which, though yet leaving much to be desired, will be admitted by the profession to be a decided step towards improvement, giving some hope of a better organisation of professional forces both within and without the metropolis. Taking a general glance at the architectural activity of the year, as shown in the larger and more important buildings, we find progress has been mainly in the direction of municipal, public, and ecclesiastical works, though the inception of the works themselves is in many cases anterior to the period of which we are writing. Among a few important structures whose completion or commencement calls for notice in our yearly summary, we may name the Birmingham Municipal Offices, by Mr. Y. Thomason—a building of considerable dignity and of a character to compete with the other edifices of the town; the new Gothic School of Art in the same vicinity; the Yorkshire College, Leeds, from Mr. Waterhouse's design, the first stone of which was laid early in the year; the Manchester School of Art, from the designs of G. T. Redmayne, architect, illustrated by us; the Bradford Hotel, by Messrs. Andrew and Pepper; the Cavendish College, Cambridge, by Messrs. Giles and Gough; the Pavilion and Winter Garden, Blackpool, by Mr. T. Mitchell; the commencement of the New University Hall, Glasgow, from the designs of Messrs. G. G. and J. O. Scott. The Town Hall and Public Offices competition at Barrow-in-Furness, a review of which appeared at the close of our second volume for 1877, has been finally settled, and Mr. W. H. Lynn, of Belfast, the architect, has been commissioned to carry out his design, which will be found illustrated, in plan and perspective,

in our first half-yearly volume for 1878, page 316. We certainly regard this as one of the most successful Gothic designs for a municipal building erected of late years, and the author is evidently adopting the same type of Gothic which Mr. Waterhouse has so ably appropriated for the same purpose in his great work at Manchester. The Council Chamber and other departments have been judiciously marked in the main elevation, and we may add the author has displayed as much ability in Gothic as he has shown in his Classic design for the Clark Hall, Paisley—another important structure which he is engaged in carrying out at a cost of over £40,000, and of which we gave an illustration, p. 340, Vol. XXXIV. That our readers may compare results, we illustrated in the same volume Mr. T. E. Collcutt's second premiated, and Messrs. Perkins and Bulwer's third premiated design for the Barrow-in-Furness Town Hall, pp. 106 and 134. These three designs illustrate three distinct treatments of modern design—one being in a Renaissance verging on Queen Anne, and the other two in Gothic, displaying opposite tendencies of that school. Another important building of the same class, to which we have given prominence, is the Reading Town Hall. Our review of these designs appeared at the close of 1877, and during the past twelve months we have given two of the premiated designs, Messrs. Alexander and Henman's, p. 596, Vol. XXXIV., and Mr. W. T. Sam's, p. 158. The unfortunate and abortive result of this competition will remain another warning to competing architects that, after all their labour, an outside architect may be employed to carry out the work. The design of Mr. J. V. Pearce, for the Great Yarmouth Public Offices, has been also selected during the past year, and was illustrated in our pages (see p. 318 of the last volume), besides the second and third premiated designs, pp. 210 and 368, and others submitted by Mr. E. F. Bishopp, p. 236, and by Messrs. Bell and Roper, p. 694. Though a comparatively small building, the competition was one in which a large amount of ability was displayed, and the designs we have selected as illustrations will show that the race was a particularly close one, and the selected plans characterised by considerable merit. We have also had to record the Aston Public Buildings competition (see page 257, Vol. XXXV.), the selected design for which was by Messrs. Alexander and Henman.

Vestry-hall architecture also has been exemplified in our pages by two buildings—the Hampstead Vestry-hall, by Messrs. Kendall and Mew (see illustration, p. 502), and the amended design for the Vestry-hall at Kensington, by Mr. Robert Walker (see illustration, p. 612). There is an official stamp about both these buildings. In neither case can we award higher praise. Of the latter building we also illustrated another design in a Queen Anne style, by Mr. J. J. Stevenson and A. J. Adams, placed second by the referee (see page 468, Vol. XXXIV.). The above examples are rather typical of the more recent phase of architectural effort as applied to business wants. Among a somewhat similar class of buildings the Shakespeare Memorial Theatre, Stratford-on-Avon, has made considerable progress under the architects, Messrs. Dodgshun and Unsworth. This building we illustrated September 15, 1876. The Dublin Markets competition has been settled, and the design of Messrs. Loekwood and Mawson awarded the first premium. Among other secular buildings are the new Concert-hall, St. Leonards-on-Sea, by Messrs. Hill and Vernon; the Rotunda Theatre, Liverpool, by Mr. C. J. Phipps and E. Davis and Sons; Theatre and Opera-house, Leeds, by Mr. G. Corson.

Of ecclesiastical works a few typical buildings in embryo must be named here. We may refer to the appointment of Mr. Pearsons as architect of Truro Cathedral, some of the other designs for which we have given; the competition for a design for the Oratory Church at Brompton, won by Mr. Gribble, and which elicited much talent from few of the foremost Renaissance architects; Clane Catholic Church, Kildare, by Mr. Hague, of Dublin; St. Michael's Priory and pro-Cathedral, Hereford; while three or four of lesser size call for notice, among them we must place Mr. Pearson's splendid brick church of St. John's, Red Lion-square, a view of which we publish to-day; St. Michael's Church, Northampton, by Messrs. Burder and Baker; Christ Church, North Kensington, by Mr. J. E. K. Cutts; and Union Chapel, Islington, by Mr. James Cubitt. In some of these we notice a marked departure from conventional types, and a bold adaptation of octagon and other forms of unimpeded central areas. The adoption of a scheme of decoration for the dome of St. Paul's, upon the basis of a design prepared by the late Mr. Stevens, the sculptor, is a matter that has occupied

attention, though it cannot be pronounced satisfactory mode of commencement; while a work of more national interest—the completion of the Wellington monument, from the same artist's design—has been completed during the year.

A few conspicuous buildings and works in the metropolis call for a brief remark. The eastern block of the new Law Courts has been completed in all essentials, and the central hall and courts are being pushed forward. The Natural History Museum at Kensington is approaching completion, and we have illustrated many of the details. The Grand Hotel, Charing-cross, and some important business premises in Northumberland-avenue and along the Embankment—namely, a conspicuous Renaissance block of chambers, by Mr. J. P. St. Aubyn—have arisen during the past year; while there is a rumour of a recommencement of the Opera-house. The Strand has shown signs of architectural activity in some new premises, some for the Art Union of London, while the Gaiety Restaurant of Messrs. Spiers and Pond has been completely remodelled by Mr. Verity. The Savoy Chapel has also been re-opened. In the City, a few business and mercantile premises have been finished or commenced. The City Liberal Club, the Gresham Life Assurance offices in the Poultry, by Mr. J. J. Cole (illustrated in our last number); Bank of Scotland, Bishopsgate-street, by Mr. Chatfield Clarke; new offices of the Prudential Assurance Company, Holborn, by Mr. Waterhouse, which we have also given, besides some buildings on the Holborn Viaduct by Mr. Witherington, and a few warehouses. Street improvements have been progressing. We refer to the opening up of the thoroughfare from Oxford-street eastwards, which has cut through some dense neighbourhoods, and will tend to infuse vitality along its route. The selection of a design for a high-level Tower bridge has at length given hope of something being done to relieve the crossing traffic of the east; the freeing of the tolls of Waterloo and Charing-cross bridges are significant of other changes on both sides of the river, and already some new lines of tramway are contemplated. But perhaps the most noteworthy incident of the year is the proposal made to light certain parts of London with the electric light.

The year 1878 has been prolific of congresses of one kind and another. And of these we may say a word. Our French neighbours' great international display on the Champ-de-Mars has helped us to compare results, and shown us that our architecture and industrial art and manufacture stand fairly among those of other nations, but from a purely art point of view, the gathering cannot be taken as a criterion of our real position. Congresses at Stafford and Cheltenham have discussed various questions of nearer interest to the profession. Of actual progress we can record little, despite a few contributions towards sanitary and artistic improvement. At the Architectural Conference, held last June, a few practical papers were read and discussed on such matters as "General Building Regulations for the Kingdom," &c.; but without any definite action or a prospect of general professional concurrence. Perhaps the part of the time best occupied was that spent in the series of visits paid to the Natural History Museum, the Law Courts, St. Paul's, and Dorchester and Bridgwater Houses, full accounts of which have appeared in our pages. Archaeology, too, has been represented by interesting meetings at Northampton and Wisbech. Abroad, the Convention of American Institute of Architects have been attempting to define the responsibility and liability of architects, and the surveyors of France have also held their international congress.

Referring to the organisation of the profession, the creation of a class of "honorary associates" in the Institute must be regarded as a step towards widening the influence of architecture and its professors outside the pale of the profession. Amateurs have always strengthened the hands of the practitioner—they infuse a new life and mode of thought, and take the professional man out of the narrow groove of custom and prejudice. With regard to the new policy towards non-metropolitan members there are still two opinions, and we think a still closer union between the Institute and country members is required before any reform affecting the professional interests can be carried. The want of power and support the Institute has felt in such questions as commission, quantities, competition regulations, and architects' liabilities, is notorious; and all these matters have been left in the same unsatisfactory position, owing to the lack of co-operation experienced. Indeed, we are not sure that provincial congresses, as proposed by Mr. Waterhouse at Manchester some time ago, or Mr. Corson's idea of provincial chapters in connection with the Institute, broached in our paper, are not desirable for the purpose of bringing about a better understanding in matters of discipline and practice. Mr. Barry justly alluded in his last address to the too passive attitude of the Institute during the last few years. It has done nothing to smooth the difficulties between architect and employer—nothing to create a public interest in professional pursuits—but has rather maintained its esoteric character of unpopularity. The Council of the Institution of Civil Engineers has also fallen of late years into something of the same apathetic indifference, and its constitution has, as we have seen of late, been threatened with internal disruption. The recent regulations as regards members and associates have been also rather the partial rectification of abuses than a sign of the adoption of progressive policy. One subject that has enlisted much attention during the year is that of competition, and the remarks which fell from the lips of the President of the Institute of Architects in his opening address have called forth a series of well-merited rebukes from a large young and rising class of the profession who have not the advantage of being born with a good name, or the good luck to belong to the Institute Council. Whichever way the question is regarded, we are bound to look at the system which the favoured few would stamp out, with all its faults as a necessity of the age, and we cannot possibly see the ground upon which a choice of a name is attempted to be substituted for that of actual results. As a writer in our own pages has observed, name has overcome for some few the inertia that impedes most men in a profession; and it is hard, we think, to take away the only remaining chance of proving ability they have.

One of the "burning questions" raised during the year has been that respecting the re-roofing of St. Alban's Abbey. The controversy, while it directly concerns a particular building, has a far wider bearing. Its issue is—at what state of decay should an old and interesting edifice be considered a fit subject for restoration?—because if we can substitute a new or improved roof we may also substitute a new tower for a half-decayed one, without respect for style or age. The letters of the architects, to the restoration committee (Mr. J. O. Scott and Mr. Street) are instructive in at least two aspects—one the difference of opinion on an architectural question existing between two leading architects of the Gothic school, and the other the extraordinary liberty with which members of the same profession can assail their brethren in a matter of a purely

practical nature, resting mainly on palpable and unmistakeable evidence. Mr. J. O. Scott's communication on page 23, illustrated by the sections of the roof, will be read with interest. About the singular effusions of clever amateurs who have added the subject to their immense budget of general information we have nothing to say. They may very well be left to speak for themselves, and readers fond of perusing such will find more of them on another page.

Death has been busy in the ranks of Art and the profession. The losses have included our foremost Gothic architect (Sir G. Gilbert Scott), and one of the most successful architects of the opposite school (Mr. Sydney Smirke, R.A.), Sir Francis Grant, President of the Royal Academy, Mr. Geo. Crickshank, Mr. John Penn, Mr. C. C. Nelson, Mr. F. P. Cockerell, Mr. H. Baker, Mr. Lockwood, Mr. John Johnson, Dr. Doran, Mr. Joseph Bonomi, Mr. Charles Summers, Mr. Timothy Hevey; in science and literature Mr. George Henry Lewes, and some others to whom the profession owed much.

The new year opens under far from auspicious auguries. There is no doubt that the general dulness of trade has begun seriously to affect the building trades, though at present to a less degree than that from which other branches of industry are suffering. That the worst may have passed over us—that a speedy revival in commerce may give fresh life to art and new work to artists and art workmen of all grades and classes, with wisdom to profit by past failures and experiences—is our best New Year's wish for all our readers.

ARCHITECTURAL ACOUSTICS.

THE science of acoustics is that which treats of all matters relating to the generation, transmission, comparison, and perception of sounds, but especially of those produced by the human voice or by musical instruments. In our present paper we shall consider this science in its relation to rooms, halls, or places of worship, in which the voice of a speaker or the sounds of an orchestra have to be brought to the ears of a large audience of persons.

The origin or mode of generation of every kind of sound is similar in its nature—namely, by the striking of one object against another so as to produce a concussion more or less violent, whereby a vibration or series of vibrations is produced either in the air or in a solid or liquid material, which surrounds the instrument by which the concussions are produced. Without some medium to transmit the vibrations to our ears no sound would be perceived, however hard one body might strike against another. This can be shown by suspending a bell or musical box in the receiver of an air-pump, and when the air is exhausted no sound can be heard outside the receiver; but as the air is admitted again the sound becomes audible, and increases in intensity as the density of the air in the receiver increases. Although the air is the medium by which sound is usually conveyed to our ears, it is by no means the only one, as nearly all materials, whether solid, liquid, or gaseous, have vibrations produced in them by blows, so that by placing the ear in contact with them the sound of the blows can be distinctly heard, independently of their being conveyed to us by the air. In fact, by putting the ear to the end of a long piece of wood or metal, a very faint blow at the other end will be distinctly heard, although the vibration produced in the air may be too feeble to be perceptible to a person close by whose ear is not in contact with the wood. When a sound is produced by means of a hammer striking on an anvil, by the beat of a drum, or by drawing a bow across the strings of a violin, the vibrations or wave motions which are set up will be propagated with equal

velocity and intensity in every direction around the centre of production until they strike against some obstacle, so that the intensity of these kinds of sounds must diminish in proportion to the inverse square of the distance which they travel over, the air through which the sound travels being supposed to be perfectly still. If, however, there is a current or wind moving in any direction through the air, it will have a great influence upon the intensity of the sound, strengthening it in the direction towards which the current is moving, and weakening it in the opposite direction. This is commonly noticed in the open air, where the wind has a powerful effect on the intensity with which we hear distant sounds, such as the discharge of artillery, the ringing of bells, or the music of a band, so that we are able by experience to determine the direction in which the wind is blowing by the greater or less distinctness with which we hear those sounds.

When the sound is produced by the human voice, or by any wind instrument, the intensity will not be the same in every direction, but will be greatest in that towards which the mouth of the speaker or of the instrument is directed, and will be least in the opposite direction or behind the speaker or performer, varying on each side according to the angle which any direction makes with the line of the greatest force. If a current of air flows against the face of the speaker the intensity of the sound in front will be diminished, while that of the waves behind him will be strengthened; while, on the contrary, a wind blowing at his back will strengthen the sound to those in front and weaken it to those behind him; consequently, the part of his hearers who are facing him will hear better, and those in the rear worse than when the air was still.

The intensity of sound is also dependent on the density of the air by which it is propagated, being very weak in highly rarefied air, and getting stronger as the density increases, so that it may be considered to vary with the height of the barometer. The presence of aqueous vapour in the air has a great tendency to weaken the sounds produced, as also is the case when the atmosphere consists of layers of air at different temperatures, or of varying densities—the kind of air in which sound is best heard being dry, still, and cold. The proximity of sonorous bodies to the origin of the sound tend greatly to strengthen it, as in the violin the body forms a box, in which the air vibrates in unison with the strings, the sounds produced by which would otherwise be scarcely heard at any distance from the performer; so also by placing hollow vessels of metal or wood near a speaker the sound of his voice may be greatly strengthened.

The velocity with which sound is propagated is very nearly the same for all degrees of intensity in the same medium, being in atmospheric air about 1,100 feet per second, whether it is dense or rarefied. In other gases the velocity varies very nearly in the inverse ratio of the square root of their density, being about 850 feet per second in carbonic acid, the heaviest, and 4,160 in hydrogen, the lightest of known gases. It has been found by experiment that when explosions of large quantities of gunpowder take place the velocity of propagation of the noise is considerably greater than when smaller charges are used; but in considering the velocity of sounds produced in a building, however large, we may take it for granted that all sounds, whether weak or strong, travel with the same velocities, there being no difference which can be perceived by the ear. When sound is produced under water the velocity of propagation in the water itself is about $4\frac{1}{2}$ times the velocity in air. The metals

and woods convey sound with great rapidity; in woods the velocity is greater in the direction of the fibres that cross the grain, being in pine 9 times that in air, in oak $11\frac{1}{2}$ times, and in fir nearly 14 times, while in iron the velocity of sound is 15 times the velocity in air.

The reflexion of sound is one of the most important phenomena in connection with the science of acoustics, as without it a speaker would find it as difficult to make himself heard in a room as in the open air. When the sound waves impinge upon a hard flat surface at any angle of inclination they will be reflected from it at a similar angle, but on the opposite side of the perpendicular to the surface at the point of their incidence, following in this respect the law of the reflection of rays of light; so that, if the direction of a sound wave which strikes on a plane surface is 45° with the perpendicular thereto, there will be a right angle between the direction of the impinging wave and that of the reflected one. If the wave strikes perpendicularly on a hard surface it will be reflected back in the same line as that in which it was moving, but in an opposite direction; hence it follows that when the distance of the reflecting surface is sufficiently great the speaker's words will return to him after a certain interval of time, and thus produce the phenomenon of echo. When this distance is 100 feet the time of going and returning will be $\frac{2}{11}$ ths of a second, which is too short a time to make the direct and reflected sounds distinctly audible to the ear, so that the original sound would in this case be strengthened by the reflected one. When, however, the distance is much greater than 100 feet, the echo will be heard by the speaker in such a manner as to interfere with the words which he utters with his mouth. The effects produced by the reflection of sound depend very much upon the kind of material which forms the reflector. If it is non-resonant—that is to say, hard and unyielding, as stone, marble, or brick—the reflected sound will be hard and sharp, as in the case of echoes generally; but when the material is resonant, or elastic, like thin and hollow wood or metal, the wave of sound communicates its vibratory motion to the substance itself, which it strikes, and this carries it along at a much greater velocity than the air wave moved with; at the same time a portion only of the sound is reflected, and is therefore very much modulated in tone. Sound waves striking on a smooth, flat, or convex surface at a low angle, are not always reflected, but appear to glide along the surface, especially when it is polished or very smooth. When the undulations impinge on a concave surface as a portion of a sphere or paraboloid, the reflected waves will be brought to a focus, as in the case of light—the focus of a segment of a sphere being at a point halfway between the centre of the surface and the centre of curvature; in the paraboloid it will be at the point called by geometers the focus of the generating curve. Conversely, if the sound emanates from the focus of either of these curved surfaces, it will be reflected from them in a direction nearly parallel to the axis of the reflector. In order, however, to produce these effects we must make the reflector of some resonant material—for when the waves meet with a soft inelastic substance, such as woollen or other cloths, their vibration is destroyed by the fibres of the cloth, and no reflection takes place.

Having thus briefly considered the laws of the propagation and reflection of sounds, let us now see how the knowledge they afford us can be applied to assist the architect in the designing and construction of buildings in which the sound of the human voice, or of musical instruments, has to be conveyed to the ears of an audience

of persons, as in churches, lecture-rooms, music-halls, and theatres—the arrangement, proportion, and materials of which have a great influence upon their acoustic properties.

The main object to be kept in view in building a room in which public speaking is to be heard is the avoidance of all material and arrangement that might interfere with or deaden the waves of sound as they proceed from the speaker to the audience, at the same time providing that the walls, roof, and floors shall be formed of such material as shall assist the voice by reflecting and conveying the sound which impinges upon them. Since the intensity of the sound has been shown to be weakest immediately in the rear of the speaker, it will be found advantageous to introduce as much resonant material as possible in this part of the room; thus in a church it would be well to have the chancel very much lower than the nave, and to form the roof of a polygonal or cylindrical shape, ceiled with thin and well-seasoned boards, laid longitudinal or parallel to the axis of the building. The walls also should be lined with thin wood as high as possible above the head of the speaker, with a hollow space between the woodwork and the wall. When the organ is placed in the chancel, or in any part behind the speaker, it will have a considerable tendency to strengthen his voice. A canopy of resonant material, of a slightly convex form, should always be placed a few feet above the speaker, when the room in which he stands is lofty, as it prevents much of the sound of his voice from being lost in the roof by throwing it down upon the audience.

It will be found advantageous to place the windows of the auditorium as high up above the floor as possible, and to line the walls from the floor to the window-sills with thin, well-dried wood, fixed with a hollow space behind it, and to avoid all recesses in the side walls, as these have a great tendency to break up the waves of sound. If the wall at the end opposite the speaker is flat its surface should be broken up by piers and recesses, or curtains might be placed at this part so as to prevent the echo of his voice from returning to the speaker's ear. Placing an organ at this end of a church should always be avoided, as it has a great reverberatory power. The ceiling of the auditorium should be covered with boarding, and the timbers of the roof should never be left open to the ridge, a polygonal or curved ceiling being best for conveying and reflecting sound. Vaulted ceilings of stone or brick ought never to be used where the human voice has to be heard by a large audience. The floor of the auditorium should be made to slope upwards, and the seats to rise one above the other, so that the persons sitting near the speaker should not intercept his voice from those further back. It is never well to elevate a speaker much above any part of his audience, as the voice can be thrown upwards with much less effort than it can be directed downwards. Concave reflectors have been sometimes placed behind a speaker to give greater effect to his voice, but they require that his mouth shall be always kept at the focus, and while they direct the sounds too powerfully upon the hearers immediately in front, they weaken them to those on the side and in the rear; at the same time, they bring all the whisperings and other slight sounds produced at the end of the room in a concentrated form to the speaker's ears. For these reasons they have generally been discarded as a hindrance rather than a help.

We have seen in the early part of this paper that the intensity of sound is greatly influenced by currents of air: every precaution should, therefore, be taken to prevent the introduction of these into a room where a lecture or sermon is being delivered, and

especially to avoid any such current from blowing towards the face of the speaker. The temperature of the air ought to be kept as uniform as possible in all parts of the room, good ventilation being favourable to its acoustic properties, so that the air shall not form into layers of different densities. The air should also be kept as dry as possible since the presence of aqueous vapour impedes the waves of sound. All external air should, therefore, be excluded in damp weather until it has been dried by passing through a warming apparatus, and a constant supply of dry air thrown into the room to remove the damp that arises from respiration.

In order that an auditorium may have good acoustic properties, its proportions of breadth, height, and length should be in the ratio of any three of the harmonic numbers 2, 3, 4, and 5, a very little deviation from which will often make a serious difference in the ease with which the speaker is heard.

The best form of plan for the auditorium of a lecture theatre appears to be that of a horse-shoe or a stilted semi-circle, the seats being arranged in concentric circles, rising one above the other in such a manner that none of the audience in front shall obstruct the sound from those behind. The lecturer should be only slightly elevated above the lowest row of the audience, and should be placed in a slight recess, the ceiling of which should be sloped backwards, and the walls covered with resonant material. The ceiling of the auditorium should be coved and formed of thin boards, and the same material used as a lining to the walls. Both floor and ceiling should have a hollow space behind them. Recesses and projections ought to be avoided as much as possible.

Where a room is intended chiefly for musical performances it is not necessary or desirable to have so much resonant material in the auditorium as in the case of the lecture-hall, since there is a greater volume of sound produced, which, in a room of moderate size, requires deadening rather than strengthening; but the parts around the orchestra should be made as resonant as possible, the ceiling over it being much lower than that of the auditorium, and sloped or curved backwards so as to assist in throwing the sound forwards. For large concert-halls the circular or elliptic form of plan appears to give the best effects, the rectangular form, with square corners, being the worst. A boarded ceiling is always preferable to one of plaster, and the polygonal or curved form to the flat one. In a large room, on the elliptical plan, a speaker placed at one focus of the ellipse will be distinctly heard in all parts, provided the walls, ceiling, and floor are formed of resonant materials in such manner as we have described.

In lofty rooms a gallery often has a beneficial effect on the sound, especially if placed at the end opposite the speaker or orchestra. Side galleries, in an oblong room, may also be beneficial, provided they are not constructed with too great a projection from the wall; the front being made of wood and its surface free from projections.

It is generally observed that a room may be a very good one for hearing in when crowded with people, but if the audience is only a scanty one there is an unpleasant amount of resonance, which makes it difficult to understand the speaker or enjoy the music; this difference arises from the clothes of the audience acting as a damper to the sound and deadening much of the reverberation from the walls and other parts of the room when it is filled with people, which is not the case when only a small number of persons is present. Too great resonance, however, should be always avoided in rooms of this kind, and it can always be prevented by the free use of

woollen material in the form of curtains or other hangings in the parts of the room most remote from the speaker. In designing a public room, however, the architect should keep in mind the object for which it is intended to be used, and by a little attention to the arrangement of its parts and the selection of his materials, he will find no difficulty in producing a building in which an auditory may listen to a speaker without straining their attention, or enjoy music without being deafened by reverberations.

THE GROSVENOR GALLERY.

THE winter collection of drawings by the old masters at the Grosvenor Gallery sustains the reputation that has been already won for this recently-established institution. Sir Comtts Lindsay has also judiciously brought together in one gallery a few of the water-colour drawings by living masters of the British school as a complement to the collection of last year, illustrating the history of water-colour painting in England. One of the choicest morsels of mediæval painting consists of two quaint line drawings on vellum, shaded in bistre of a brown tone—one representing a king on horseback receiving the keys of a city, and another of the same size representing a king on his death-bed surrounded by his children and courtiers. The conception is probably derived from the old fable of a "Bundle of Sticks." Red is freely used in the dresses; and the figures, though of conventional stiffness, are remarkably well drawn, especially the faces. This work is dated about 1470, and belongs to the Early French school. No. 11 is a composition sketch for a spandrel of a draped female figure, assigned to Giulio Pippi or Romano, as he is called, about the 16th century. The work, like most of the collection, is a pen drawing shaded with bistre. Andrea Mantegna (1431—1506) is represented by several excellent subjects—one, a study, entitled in the catalogue "Combat of Marine Deities," lent by J. C. Robinson, Esq. The two bistre sketches on vellum of SS. Peter and John (20), ascribed to Giovanni Bellini, are spirited figures. Some of the water-colour washing has peeled off in places. Of a Decorative character is "St. Luke and St. John," in red and white chalk, by Pierino del Vaga (1500—1547); but a more remarkably fine drawing is 23, "The Entombment," by Andrea Mantegna. It is a bistre drawing upon brown paper, and is the original of the engraving by the artist. Every line and touch is perfect, and the work is exceedingly well finished. A design for a chalice by the same master (35) is also highly-finished in detail, drawn in bistre. The chalice has a plain bowl, with a band of engraved work, a rich octagon-shaped knob with figures, and the foot scalloped. It has been engraved by Hollar. Various other studies and compositions of this artist are exhibited. The "Head of the Laocöon," by A. Carracci (1560-1609), is a bold colossal size sketch in black chalk on brown paper, in which there is much expression. One very interesting architectural drawing is No. 52, "Finished Design for the Sedilia of a Church," ascribed to Bramante. The composition is a Renaissance series of pilasters and openings in five bays drawn in sepia and shaded with blue. A clever composition is "The Birth of St. John the Baptist," by Carlo Cignani (1628-1719), a bistre sketch, heightened with white, on dark paper. The loans to the collection by Robert R. Roupell, Esq., are particularly valuable. We note also a figure of a Saint, probably St. John, holding a book, assigned to L. Ghilberti (1381-1485). The drawing is silver point on an olive green ground shaded with bistre and touched up with white (60).

No. 64, a group of three figures in adoration of an angel, by Luca Signorelli, is interesting. It has squares over it for the purpose of enlarging, and it is said to be the study for the author's "Nativity," painted in 1496, or a portion of it. The sketches in sepia, touched with white, on brown paper, by Filippino Lippi (Nos. 69, 70, and 71), are exceedingly vigorous and spirited, displaying excellent grouping, as in "Adoration of the Magi." The "Virgin and Child," by Parmigiano, is a very fine study in bistre. Leonardo da Vinci is well represented in allegorical subjects, portrait studies, and drapery; these are chiefly in black chalk, on brown or blue paper, heightened with white. "The Virgin and Child" (93) and the "Grotesque Head" (94) are vigorous. Most of these have been lent by Christ Church College, Oxford. Various interesting sketches and studies of heads and groups are exhibited, ascribed to Correggio (1493-1534). We particularly notice 109, an exquisitely-finished drawing in black and red chalk of "Virgin and Child," the colours having gone; 105, a composition in pen and ink, and 110—figure of "St. Peter and other Apostles, seated on Clouds"—a good composition. No. 130 is a fine head of a woman by Titian, life-size; the face turned partly round: in black and red chalk. No. 159, a fine composition for a series of studies in oil, for a large picture in the Florence Gallery, representing a "Triumphal Procession of Henry IV.," by Peter Paul Rubens; also a "Group of Amorini," in sepia, by Sir Anthony Van Dyck (59). A "Bacchanalian Procession," by Rubens (164), is a clever group; so is 168, "Two Apostles," a conception marked with much vigour both in figures and drapery. By the same master is "Venus leading Cupid" (186), a water-colour drawing. That admirable painter Canaletto (1697-1768), is represented by a fine architectural sketch of a "Roman Bridge in Ruins" (190), drawn boldly in sepia, and washed in colour. The same artist's "View of Old Westminster Bridge, with the Abbey" (384), is still more admirable as an effective drawing in India ink shading with brown lines, in which we are led to think how well suited for architectural effects the ink and simply washed sketches were of the last century. See also 386, a pen and washed sketch of a building. Of other studies we may mention the "Judgment of Paris" (193), by Van Dyck; Rembrandt's sketch of a "Young Woman Sleeping" (201), in which a few strokes of the brush produce a telling effect in the drapery; his "Angel Appearing to Peter" (217), a striking sketch, boldly washed in sepia; "Village on Bank of River" (223); Dusart's "Boors Playing Backgammon in an Alehouse," finished in colour (233); Van Ostade's "Front of a Tavern" (241); "Design for a Saltcellar" (330), by Titian, a pleasing conception in red chalk; "Dutch Interiors," by Jan Steen; also an "Interior of a Dutch Cabaret," by Van Ostade (344), wonderful in vigour and effect; some pieces by Teniers, Cuyp, and Van der Velde; a very charming landscape study of trees in chalk, lightly washed in colour on grey paper, by Anthony Waterloo (1618—1679); a spirited red tinted sketch of the "Adoration of Shepherds," by Veronese; also some decorative figures, suggestive for spandrel or pediments (378); a charming and feeling sketch of Venice, by Francesco Guardi (383); a rough but spirited bistre sketch of "A Baptism," by Donatelli (391); studies by Leonardo da Vinci (397); and some singularly instructive sketch diagrams of figures, showing rules for proportioning the figure, by Andrea del Verocchio, said to be those given to his pupil Leonardo da Vinci (Nos. 401 and 402). In these we find the length of foot is given as one modulus, and the span of hand as another measure. We

must not overlook also some fine studies by Perugino, lent by Mr. James Knowles; a design for a ceiling by Velasquez (463); a water-colour sketch of avenue, by Watteau; "The Dream of Human Life" (497); and a cartoon for a colossal representation of Charity, drawn in black chalk on brown paper with all the vigour and animation characteristic of that great master of the figure, Michael Angelo.

Passing to the water-colour gallery, by artists of the British school, we find the works of such eminent masters as E. J. Poynter, Smallfield, Alma Tadema, Marsh, Sir Coutts Lindsay and Lady Lindsay, Gow, Wolf, Bongh, Corbould, Lockhart, Macallum, Orrock, Hine, T. Danby, Dobson, Carl Haag, Frupp, Marks, A. W. Hunt, Hubert Herkomer, Linton, Crane, Whymper, and others. Mr. Poynter, in his "Venus and Æsculapius" (794), and other drawings, exhibits the finished conceptions of the master, which contrast by proximity to other bolder handling. Mr. A. H. Marsh, in his "Mussel-banks on the Conway" (799) charms by the rich tones of his banks, as in 801 he does by the vigour and freshness of the young ruddy mussel-gatherer. "The Pet of the Crew," by E. G. Gregory, is a conscientiously drawn and finished picture, bespeaking its story very well; while Mr. Parker's "View at Hurley, Bucks," and his "Hurley Lock" (813), are bright, sunny, spring-like pieces, in which the artist has employed body colour. In the last picture the figures of boys, and the lock and light foliage in the background, are inimitably finished. Particularly facetious is A. C. Gow's "Lord Foppington's Levée" (814). The servile expressions of the attendants just entering the bed-chamber, and the anxious look of the fop—in his dressing-gown, seated by a toilet table—as he looks back, are as excellent as the bedstead chintz and the chimney-piece and oak-panelling of the room. A fancy drawing-room piece is entitled "The Sleepers"—a young girl, clad in a muslin dress, with scarlet sash, lying on a couch, with a kitten, fast asleep also, on her breast (815). We have seldom seen a cleverer study of a rough sea than Mr. Powell's sketch (828) of "A Grey Day at Sea." The huge trough and the smaller ripples are as true to nature as the colouring. Close to it is a small sketch ("A Misty Morning," by Mr. F. Powell), exceedingly simple, but the mist on the water and the aerial perspective are illuively real. We note also "Anstruther," a richly-coloured landscape, by Sam. Bough, R.S.A. (833); another very conscientious landscape by the same artist ("Hamilton," 835); Mr. Lockhart's "Water Gate of the Inquisition, Spain"—a spirited drawing, clearly coloured; Mr. Walton's "Cover Wood"—rich in autumn tints; and, especially, Mr. H. Macallum's "Return of the Beer Fleet" (852), which, for the figures of fishermen, the boat grouping, and colour, can hardly be surpassed. Mr. W. C. Dobson's "Young Nurse" (864) is a pleasing study of children's faces without artifice; and Mr. Hine's "View of Downs near Lewes" is equally truthful in its soft rendering of undulating downs such as we see them in Sussex. Aerial in its colouring is a lake scene by T. Danby (872), contrasting with "Wave by Moonlight," by A. Severn. No. 884 ("Gipsies"), by Mr. R. W. Macbeth, is a bright study, well finished, of a shady orchard, with a gipsy fiddler, to whose tune two gipsy women are listening intently. Mr. Albert Goodwin is represented by two striking pieces—"Verona" (889), a rich study of colour in the Campanile—so lauded by Ruskin—and the painted house fronts, and in "Abingdon Churchyard," with its fine wooden verandah. No. 908 ("Meeting on the Turret Stair") sounds like a mediæval tale. Told by Mr. F. Burton, it shows a warrior, clad in chain

armour, meeting a young woman, whose face is turned in anguish of despair. A few drawings of architectural subjects must be noticed. "Where stood Bridewell Hospital and Prison" (913), by Mr. G. P. Boyce, is a faithful rendering of St. Bride's steeple and the old brick houses from the deserted site. That well-known painter, Carl Haag, in his "Entrance to a Kahn, Jerusalem," has shown the power of his pencil, and there is a depth of tone in the crypt-like vault. His "Acropoliss" (925) is a sensationally striking picture of the marble citadel and limestone buildings with the plains and hills beyond, the rock and temples bathed in a ruddy glow which almost unnaturally contrasts with the purple distance. Mr. A. D. Frupp is an artist whose works have always a charm of unaffected truthfulness in detail. His "Old Church Porch, Dorset" (934) is an admirable drawing of a beautiful wooden porch, which the artist has reproduced with all the effect of the grey time-stains and clefts in the oak, blending happily with the red tile roofing. In the same class we place Mr. John O'Connor's "Priory, Hampstead" (1018), a fine Elizabethan portal and front; its grey stone carving and the background of gables being most skilfully and feelingly handled in colour. Equally bold and effective is the "Old York Gate," by the same artist. We can only mention a few other pictures striking for qualities of drawing or colour. Mr. T. R. Lamont's "Bonny Kilmenny" (947), in three tableaux, is a pathetic story or legend told with much tenderness; Mr. Buckman's "North Country Wrestling" (938), a decorative treatment; 948, "A Backwater on the Thames," by Mr. E. Fahey; Mr. Mark's "What Is It," some rainbow-coloured pieces, by Mr. A. W. Hunt, as "Durham" and "Loch Torriden" (956-7) exceedingly soft and brilliant; clear and carefully handled drawings, by G. Frupp (972-980); an expressive miniature piece, entitled "Weary," by H. Herkomer, and a few clever and striking landscapes, by Mr. H. S. Hine, P. F. Naftel, J. W. Whymper, T. Danby, R. W. Macbeth, Otto Weber, and J. Orrock. We have not touched the Sculpture Gallery, filled as it is with studies by Domenichino, Raphael, Albert Dürer, and some choice sketches of the Venetian, German, and Early Flemish school. The collection of drawings by J. A. D. Ingres (1780-1867) is unique of its kind, and is well worth a separate visit.

CANAL AND CULVERT TABLES.*

THERE have been considerable difficulties in the way of adopting an accurate formula for calculating discharges and velocities in rivers, canals, and culverts, and Mr. Lewis D'A. Jackson, A.M.I.C.E., the author of "Hydraulic Manual and Statistics," previously reviewed in these pages, has calculated and compiled a collection of tables based on the formula of Herr Kutter, now recognised as the most correct. The tables of Mr. Jackson are intended for practical use, and the author has attempted to meet the requirements for greater accuracy than has been usually found in treatises of this sort. The gradation of quality of surface and irregularity of course are important elements in such an investigation; but Kutter's formula is so complex and involved that we hail some work giving tables that may be referred to by the practical engineer. The main object of the tables is to afford a ready determination of mean velocities and discharges (which are given in feet and cubic feet per second) to suit various sections, conditions of surface, regularity, and hydraulic inclinations in all ordinary cases. The mean velocities and discharges in Tables VI. and VII. do not apply to heads of pressure, but to conditions in which the pipe runs full-bore without "heading up." Kutter's general values, or co-efficients of roughness and irregu-

larity, are not considered perfect by the author, who assigns the following values of the coefficient of roughness (N) for artificial materials:—

1. Smooth plaster and glazed material	0.010
2. Ashlar, brickwork, cast and wrought iron, unglazed pottery	0.013
3. Rubble	0.017

In the tables given sewers of circular form, ovoidal section, as used by Hawksley, and the Metropolitan pattern, together with the peg-top section of the author, are adopted, the latter being considered better to insure greater scour, and to prevent the lodgment of sediment. The sides of this form are straight. Valuable sectional data are given in Table IV., in which the sectional areas, hydraulic radii in feet for pipes of these sections are stated. Thus we find on reference to it, that in Hawksley's ovoid culvert of 2ft. transverse diameter, under head "Full," the sectional area is 3.9820, the hydraulic radius 0.5532; when two-thirds full the area is 2.6856, and the radius 0.620, and when one-third full the area is 1.0276 and the radius 0.396. Table VI. gives mean velocities of discharge in feet per second, quantities discharged in cubic feet per second, and coefficients of mean velocity for culverts and pipes of various sections in cast or wrought iron, brickwork, and stoneware. We cannot give in a brief notice a fair account of all these tables, but we can recommend Mr. Jackson's work to the practical engineer as one of the most reliable of textbooks in this branch of engineering.

COMPETITIONS.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The board of management some few months ago invited Messrs. Batterbury and Huxley, Mr. M. P. Manning, and Mr. F. W. Stent, to submit in competition plans for rebuilding the above-named hospital in Queen-square. The board have decided to adopt the plans submitted by Mr. M. P. Manning, of Mitre-court, Temple. The honorarium to the other competing architects was fixed at fifty guineas.

SWINDON BOARD SCHOOLS.—At the meeting of the Swindon School Board last week it was reported that no fewer than 162 letters had been received in response to a preliminary advertisement inviting architects to send in plans for the proposed new schools. A long discussion ensued on the general question of throwing the competition open to all comers or confining it to local men. Several members spoke in high terms of the work that had been carried out at Stratton and elsewhere by local men, but an opinion was expressed that the requirements would be met at a lower cost if all architects were allowed to compete. Eventually the matter was referred to a committee.

A new Baptist chapel and schoolroom are in course of erection at Blackley, near Halifax. The chapel will accommodate 500 adults, and 240 children. The fittings are of pitch pine varnished, and will be ready for occupation in June next. Beneath is a schoolroom, which is so far completed that it was opened last week. It will hold from 350 to 400, and adjoining are superintendent's vestry, serving kitchen, store-room, and heating apparatus room; above are ministers', deacons', and singers' vestries. The architect is Mr. C. F. L. Horsfall, of Halifax, and the contractors are—masons, Mr. T. Bottomley, Elland; joiners, Messrs. Hurst and Wilson, Elland; glazing, Mr. J. Bolton, Halifax; heating apparatus, Mr. J. Calvert, West Vale. The total cost will be about £3,500.

The premises of Messrs. J. Beal and Co., the well-known Brighton newsagents, have been reconstructed, under the supervision of Mr. Arthur Loader, architect, of Brighton. Mr. G. R. Lockyer being the builder. The cost of the work has been £2,000.

An exhibition of works by the students of the Halifax School of Art is on view at the Mechanics' Hall in that town. They include three oil and prize works, and many water-colour, pencil, and crayon drawings, but the chief feature in the exhibition is the pictures by Mr. Stopford, the headmaster, of which there are twenty-two, embracing scenery in Ireland, Wales, and on the English coast.

* Canal and Culvert Tables, under a modified classification. By LEWIS D'A. JACKSON, A.M.I.C.E. London: W. H. Allen and Co., Waterloo-place, S.W.

CHURCH OF ST. JOHN THE EVANGELIST, RED LION-SQUARE,
HOLBORN—ROYAL ACADEMY PRIZE DESIGN FOR A TOWN
HALL—THE ENTRANCE GATEWAY TO SOMERSET HOUSE
—VILLAS AT GREEN HILL, HAMPSHIRE—NEW PREMISES
IN WOOD-STREET.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ROYAL ACADEMY TRAVELLING STUDENTSHIP
DESIGN FOR PROVINCIAL TOWN HALL.

THESE drawings, for which the studentship has
been awarded, were made within the Academy
during the month of October, according to the

ment. As it is probable that such a building
would be heated by other means than open fire-
places, these have been intentionally omitted
throughout, which accounts for the absence of
chimneys in the design. The accommodation
provided is slightly in excess of the conditions,
without occupying the whole of the given area
of site.—W. S.

ST. JOHN'S, RED LION-SQUARE, HOLBORN.

THIS perspective view and the ground plan
will show the design and arrangement of this
church more completely than any written
description could do, and therefore it will only
be necessary to give some of the leading
dimensions, and to describe the nature of the
materials which have been used in the build-
ings. The chancel is 34ft. by 20ft., and, in-
cluding its aisles, 40ft. wide; the morning
chapel 17ft. by 40ft. long; the nave 38ft. 6in.
by 74ft. long, and, with its aisles, 82ft. wide.
Height of nave and chancel, 54ft.; height of
aisles, 20ft.; height of chapel, 22ft. The
material used for the dressings is Bath stone,
both inside and out. The facing to the outside
is of red brick, and to the inside of picked
stocks. The church, in every part is groined,
the ribs of Bath stone, and the spandrels filled
in with stock bricks. The object being to pro-
vide as much accommodation as possible, every

Royal Academy, and, as measured details of
one of the best works of that distinguished
architect, Sir William Chambers, they will, we
are sure, be valued by our readers. Our illus-
trations to-day show one bay (the central one)
of the longitudinal section and elevation of the
entrance to the courtyard of Somerset House
from the Strand, and one bay of the cross
section looking towards the Strand, and giving
a section of the central doorway to the Strand
wing on the right-hand side of the entrance,
originally used by the Royal and Antiquarian
Societies. We also give a plan looking up of
the soffit of one of the cross arches. There are
on plan three bays each way, the central one
crossways being used for carriages, those on
either side being for footways. The following
notes have been sent us by Mr. Gibson, who
also remarks that all the work, ceiling, &c.,
above the main cornice is executed in plaster.
Much of the delicate detail is lost in reality on
account of the shadow of the entrance arches.
(At an early date we shall give some of the
enrichments to a larger scale.) *Notes to the
drawings:* The setting out of plan is not quite
rectangular. The piers on each side of the
centre openings of fronts are before the general
line, which is, however, followed by the arches
over. The two side piers of Strand front are
narrower than the two centre piers. The

usual regulations. Being done, to a certain
extent, "against time," there was little oppor-
tunity for careful thought, either in plan or
elevation, and while not wishing to escape
criticism, the author is conscious of several weak
points in the design. The plan is arranged
so as to isolate, as far as possible, the three
main divisions of the building (each having a
separate entrance, &c.), and at the same time
to afford complete intercommunication when
desired. This is effected by means of a central
area, round which is a corridor divided by
grilles, so as not to interfere with light and
air. The sessions court is placed on the north
side, and the assembly-room on the south; the
principal entrance, hall, and council chamber
on the west; while on the east are the mayor's
suite of apartments (with private entrance and
staircase), and the access to police offices, fire-
engine, &c., which are provided for in the base-

inch of the site has been covered by the
church. The outline of the church is conse-
quently of a very varied nature, owing to the
adjoining properties against which it has been
made to fit, and there are many peculiarities
about the church which have originated out of
this irregular site and the necessities of the
case. The architect of the building is Mr. J.
L. Pearson, A.R.A. References to plan:—

ENTRANCE GATEWAY, SOMERSET HOUSE.

WE reproduce to-day a portion of the drawings
for which the Royal Academy have just
awarded their first medal for 1878 to Mr. R. W.
Gibson. The care and spirit of these drawings
have seldom been equalled by students at the

columns are not exactly alike in diameters;
some are slightly larger at 5ft. height than at
base, but this seems to be accidental. Some of
the columns are a little out of perpendicular.
The bases to columns slightly vary in projec-
tions, but are nearly all larger than those to
pilasters. In one or two cases the face of
architrave is not quite over the face of column,
as seems to be intended. The cornices upon
walls have less projection than those to middle
aisle; other mouldings also vary. The drawings
(details) are medium examples of three or four
measurements. The curves were ascertained
by the cymagraph. The spring of vaults is not
always exactly over centre of column, but this
seems to be accidental and irregular. The
lines of vaulted ceiling decoration do not in all
cases range as intended, and the dimensions of
corresponding parts vary a little. The pave-
ments are not quite level.

VILLAS, GREEN-HILL, HAMPSTEAD.

THESE villas, of which an illustration is given in our present issue, are now in course of erection in this favoured suburb. The style popularly known as "Queen Anne" is here treated with considerable modification, the object apparently being to retain the homely picturesque feeling, without sacrifice of light, and with economy of cost in plan and detail. The walls are faced with pressed bricks made in Leicestershire, not perhaps as rich in colour as some would desire, but selected in this instance for their good weather-resisting qualities. The strings and cornices are of moulded bricks from the same district. The roofs are covered with red Broseley tiles. Mr. Theodore K. Green is the architect.

NOS. 50, 51, AND 52, WOOD-STREET.

THIS warehouse forms part of the extensive premises belonging to Messrs. Rylands and Sons, Limited. The elevation has been considerably altered, and, as will be seen by our illustration, the old height preserved. While this has cramped the design the architects have preserved the number of stories by setting back the upper floors. A good light has been obtained throughout by the arrangement of the areas and bulkheads. The builders were

ST ALBAN'S CATHEDRAL.

I HAVE read Mr. Street's letter on this subject with interest, if not with pleasure. To my mind it savours too much of those sermons in which the preacher creates a bogie of unbelief for the mere pleasure of knocking him down. I have no intention of replying in detail to what Mr. Street urges, for I am well aware that if the controversy between us were continued indefinitely, neither would be convinced of the error of his ways; and on the whole I think it is one of those frequent cases in which it is best to "agree to differ." Nevertheless, there are one or two matters which I must take note of.

I have already expressed to Mr. Street my regret at having used the unlucky word "surreptitious," and have explained to him that in writing it I had no thought of its having reference to himself, but only to the action of an uncalled-for doctor examining a patient without his or his friends' knowledge. I did not see at the time how easily the word might be misunderstood.

Mr. Street evidently still thinks that my conduct has been inconsistent with my oft-

Sir Gilbert Scott, that the old roof should in that case be repaired, and that over it should be erected a new set of framed rafters to the higher angle, while, about the retention of the ceiling, there can hardly arise any question. Sir Gilbert's wish was, supposing the higher angle to be agreed on, to follow exactly the same course adopted by him at Selby in a parallel case. This has been perfectly successful, and may be taken as a precedent."

It will be seen from the above that, although from a feeling that this had not become a practical question, I did not urge the high roof as a "*sine qua non*," yet the bias of my opinion was all in favour of it. This report, and its supplement, dated June 25th, were read together at the meeting of the Committee held on June 29th. I was present, and, in the discussion which took place, spoke strongly in favour of a high roof being erected above the timbers of the old one, and finally the high roof was carried. The minority, however, not being satisfied, a larger meeting was called for the 10th of August. For this meeting I prepared a report, dated July 26th, giving various estimates for the high roof, which I

FIG. 2.

Messrs. Braid and Co., of Chelsea; Mr. James Mudie was the foreman. The carving was executed by Mr. J. W. Seal, of Walworth, and the whole was carried out from the designs and under the superintendence of Messrs. J. and J. Belcher, of 5, Adelaide-place, London-bridge, E.C.

THE ARCHITECTURAL SCHOOL—ROYAL ACADEMY.

THE following are the admissions to the Royal Academy Architectural School for January, 1879:—

1st Class Student.—W. Stevens.

2nd Class Students.—F. W. Besant, C. Bradley, G. H. Coldwell, H. Goodall, M. J. Lansdell, F. C. Lees, A. J. Murray, J. B. Phillips, L. Stokes, T. Watson, T. B. Whinney.

Probationers.—F. C. Booty, F. G. F. Hooper, W. Lane, C. P. Leach, F. W. Littlewood, W. Bessett-Smith, N. J. Stangen, T. S. Townsend.

The first stone of the monument to the memory of Lord Brougham was laid on Thursday week at Cannes.

An English Wesleyan chapel was opened at Llan-saintffraid, near Oswestry, on Friday week. The plans were supplied by Mr. W. Ranger, of Finsbury Pavement, E.C., and the builder was Mr. John Peckstock, of Meitod, near Welshpool.

quoted report of June 25th. I have been much surprised at what has been built upon this poor letter, which begins with the words, "I understand that a further report, dealing especially with the western portions of the roof, is thought desirable. As this had already been dealt with by my father I did not include it in my former letter." This is, on the face of it, only supplementary to what had been written before. As nobody seems to have cared to inquire what this was, I think it is well to quote that portion of my original report, dated June 7th, which refers to the high roof. After stating the nature and probable cost of the repairs required to the old roof and ceiling I go on as follows:—

"The next division of the subject is perhaps the most important—namely, the treatment of the lead covering. The question of the pitch of the roof at once comes in, whether to preserve the present form, or revert to the more ancient high pitch shown by the marks remaining on the tower wall. I consider that all I have said above [i.e., as to the repairs of the old roof and ceiling] applies equally to either treatment of the roof, as, if the high pitch is determined on, I think the committee will agree with the view held so strongly by

had been instructed to obtain, and ending as follows:—

"I understand that a motion will be brought forward at the meeting, the object of which is to reverse the decision arrived at in favour of a high-pitched roof. The arguments I have heard are—(1st) that the western part of the abbey having been Tudorised—as I think it has been expressed—the low-pitched roof is more in accordance with the architecture, and (2nd) that as a new higher gable will become necessary at the west end, we shall be infringing on the design of Abbot Wheathampstead. I wish to point out that, as far as the nave is concerned, no late alteration of any consequence whatever has been made, with the exception of the insertion of the west window. It is to all interests and purposes early architecture from beginning to end, and therefore a high-pitched roof, such as it originally had, will be in full accordance with its design. Besides this I wish to call attention to the fact that the gable does not form any important feature in the west front. Its design terminates in a horizontal cornice and parapet, the gable having been erected well behind this on the inner face of the wall, with a passage way between the two. In the new arrangement no alteration will be made to the parapet beyond such repairs as are necessary, and the new

gable, which should be kept subordinate to the design, will, like the present one, be in rear of the general line of the front. Another consideration is this—the three noble portals, with their lofty gables, will doubtless be restored before long. These will greatly alter the character of the west front, vastly increasing its beauty, and there cannot be a question that the gable of the new roof will be more in agreement with the new and earlier character than the depressed gable which now exists.”

The final meeting, which was one of all the large subscribers, was held a few weeks later, when, for the third time, the high roof was carried by a large majority, but on none of these occasions was I able to carry out my wish of preserving the old roof in connection with it. This, I am glad to think, has now been made possible by the action of Mr. Street and the Society of Antiquaries, and, so far, I am extremely obliged to them. I do not think I need say anything further on this point.

Although Mr. Street's opinion is opposed to mine in some respects, I am able to gather some crumbs of comfort from his letter—for instance—although at the beginning of it he disputes my higher roof mark being a roof mark at all, and calls in Mr. Neale to help him (who, after agreeing with me as to this line at the Society of Antiquaries, and more recently at a meeting of the St. Alban's Architectural Society, has, I am told, been spending day after day amidst snow and ice, measuring the tower brick by brick, in order to prove himself and me wrong), yet later on in his letter he says (speaking of my explanation of the upper and lower roof marks) that “a far simpler explanation would be that when the nave walls were raised 3ft. 6in. above the transept walls, the ridge of the nave roof was also raised 3ft. 6in. above its old line, and so produced the ‘original’ marks above the other.” From this I gather that after all Mr. Street thinks, as I do, that these upper marks do at least indicate a roof, and are not due to my imagination, as otherwise the explanation would be far more simple than reasonable. Whether Mr. Street now agrees with me or not, as to the raising of the walls, I cannot make out from the wording of his letter. I hope he does, as I consider it proved as certainly as anything resting on architectural evidence can be.

Then, as regards the artistic effect of a high roof, Mr. Street says that, if only the old timbers were rather more rotten, he could agree “in the propriety of raising the ridges of the roofs to the level at which they stood when the tower was built.” He adds: “I should do so, because at this level it would be possible hereafter to look forward to all the roofs being, as they once were, at the same level.” (Surely not that of the eastern arm, as this would involve the destruction of the choir clerestory?) If it would be an advantage to raise the roof at all, the more or less rotten state of the timbers cannot affect the artistic propriety of doing so, nor can the difference in the height (varying from 3ft. 6in. to nothing according to the view taken of the Norman ridge line), make all the difference between dwarfing the tower and restoring it to “the proportions its builders intended that it should have.” Moreover, I am not at all prepared to believe that if Mr. Street favoured the high roof, he would favour the destruction of the parapets; so that I am able to gather that he must think as I do that the appearance will, on the whole, be improved by the high roof, and that such a roof can be erected with parapets.

Mr. Street's theory of the Norman roofs finishing below the string-course of the tower is new. His diagram, exhibited at the Society of Antiquaries, certainly did not show it so; nor are there any marks on any of the four sides of the tower suggest-

ing it. The only evidence is Mr. Neale's drawing of the transept springers, and this part of the building I am now having accurately measured.

Mr. Street states, most inaccurately, that I have “taken away whatever remained of the old corbel table, &c., on the western part of the nave, and have erected a new parapet of Early English style to agree with the old work in the clerestory.” The Early English corbel table remained here before our works of restoration were commenced, as may be seen by reference to Mr. Neale's plate. This portion has been most faithfully restored, many of the original corbels being retained; but as this part of the restoration was all done before I came on the scene, it can have little to do with my theory, and so the “*reductio ad absurdum*” falls to the ground.

The proposal to restore the high roof having met with such an unexpected reception, I tremble to think what would happen if I suggested the reinstatement of the slender Hertfordshire spire, which formed a beautiful feature, probably from Trumpington's days down to the last century; but, nevertheless, I venture to say that I should like to see it restored.

J. OLDRID SCOTT.

Mr. Scott has been good enough to lend us his drawings, specially prepared to show the relative lines of the Norman and later roofs, and also giving a section of the existing roofs and parapets to the nave and south transept of St. Alban's. The following references will at once explain the sketches:—Fig. 1 is a section of the nave, with west elevation of tower; B shows the line of original Norman roof of nave, with shingles as a covering; A shows the line of the second or later roof, and the sectional part, hatched at C, shows the existing roof; D, to the section of the walling, shows the Norman wall immediately under the tie-beams of the original roof; as shown by B; E shows the section of the later work and parapets. The span is 41ft. 2in. between parapets. F shows the ridge line of the original Norman roof to south transept. This is shown by Fig. 2, which gives the south elevation of tower, A being the line of pitch of original Norman roof; B shows the roof of later date, and C the existing roof. The span is 42ft. 3in. between the parapets.

As it is impossible to answer Sir Edmund Beckett in the *Times*, will you allow me to make public in your columns the enclosed correspondence, arising out of the remark with which he concludes his letter in that paper, under the above title, as follows:—“I could say something of the third companion's probable impartiality, too; but as it has not been published by their newspaper I will not.”—ARTHUR W. BLOMFIELD.

[Copy.]

28, Montagu-square, Dec. 25, 1878.
SIR,—I have just been looking at the brilliant display of squibs and rockets with which (so far as the *Times* is concerned) you bring “the Battle of St. Alban's” to a close this morning. I notice that it ends with the exhibition of a “cracker,” directed against myself, which only half goes off. This is highly unsatisfactory, and I think I am entitled to ask you for some explanation. It appears to me extremely unfair publicly to impute unworthy motives, or to innuendo the probability of such motives, in so vague a manner as to render distinct repudiation impossible. I therefore appeal to you to state clearly by what you believe me to have been biased in the very minor part I have played in the matter. It is sometimes difficult to feel confident as to the springs of action even in one's own case, and I undertake to tell you at once if you succeed in pointing out to me any hidden motive in what I have done beyond the ostensible one of the simple wish to give an honest opinion when pressed on both sides. I am entirely unconscious of anything more at present, and I am at a loss to conceive what you can mean.—I am, sir, your obedient servant,
ARTHUR W. BLOMFIELD.

Sir Edmund Beckett, Bart., Q.C.

On a post-card, received Dec. 27, 1878.
I never re-light my public “crackers” for private exhibition, and I am sure it is unnecessary in this case.
E. BECKETT.

60, Marina, St. Leonards.
Arthur Blomfield, Esq.

28, Montague-square, Dec. 27, 1878.
SIR,—The fair inference to be drawn from your reply to my letter is that you do not hesitate to make public insinuations which you are not prepared to substantiate.—I am, sir, your obedient servant,
ARTHUR W. BLOMFIELD.

Sir Edmund Beckett, Bart., Q.C.
I shall publish this correspondence.

60, Marina, St. Leonards, Dec. 28, 1878.
SIR,—The fairer “inference from my answer” to your letter is, that if a man behaves as you and Mr. Street and Mr. Christian have done, and then besides writes privately to me about my “squibs and crackers,” he will be “answered according to his folly.” And he will get no other answer.—Yours obediently,
EDM. BECKETT.

A. W. Blomfield, Esq.

28, Montague-square, Dec. 30, 1878.
SIR,—In “answering me according to my folly” you clearly remain yourself in the other great section of humanity. Allow me, however, to remark that the roof of the nave of St. Alban's (spell it how you like) is not your private property, though you seem to think so.—Your obedient servant,
ARTHUR W. BLOMFIELD.

Sir E. Beckett, Bart., Q.C.

OBITUARY.

THE LATE TIMOTHY HEVEY, ESQ., F.R.I.A.I.—The above name closes the obituary of Irish artists for the year just passed. Born in the county Antrim in or about the year 1844, and having been educated at the Catholic College, Belfast, he was, at the age of eighteen, articled to the late Mr. Pugin (afterwards partner of G. C. Ashlin, Esq.) and having completed his pupilage he passed some years in the office of the latter in Dublin. In the year 1869 he commenced practice for himself in his native county, and with considerable success, having since then designed and superintended the erection of many churches, parochial dwellings, schools, and manufacturing establishments in the north of Ireland, which, one and all, bear testimony to his abilities as an architect. The new church of St. Patrick, Donegal-street, Belfast, is, however, the principal work with which we find his name connected. At the time of his death, which took place on Sunday evening, the 29th ult., at Albert-street, Belfast, he was in his 34th year. He leaves a widow and one child to mourn his untimely demise.

THE LATE MR. JOHN JOHNSON.—We regret to announce the death, in his seventy-second year, of Mr. John Johnson, architect and surveyor, 14, Buckingham-street, Adelphi, W.C. The deceased was awarded a gold medal by the Society of Arts in 1833; in the following year he gained the first silver medal of the Royal Academy for architectural designs, in 1835 the Academy gold medal, and in 1836 the Academy travelling studentship in architecture, with which he travelled in Italy. In May, 1841, Mr. Johnson commenced independent practice in London, and continued in the profession until his death. He was not a member of the R.I.B.A. In December, 1875, Mr. Johnson received a diploma of honour in the arts of design from the Academy of Florence. He enjoyed a large private practice as a surveyor, but will be chiefly remembered as the joint architect with Mr. Meeson of the first Alexandra Palace on Muswell-hill (opened May 24th, 1873, and destroyed by fire on June 9th of the same year), and sole architect of the present palace, which was opened May 1st, 1875. Both buildings were fully described in our columns in the months of April and May, 1873 and 1875, and the ground plan of the present structure was reproduced by us, Feb. 6th, 1874. Amongst the churches designed and executed by Mr. Johnson may be noticed the important Late Decorated parish church of St. Edward, Romford, built in 1849, and that for St. Andrew's district, Romford, opened twelve years later; St. Paul's, Camden-town; St. Matthew, Oakley-square; St. Luke, King's-cross (removed to make way for St. Pancras-station); St. Andrew, Thornhill-square; St. Mary, Greenhithe; Christ Church, Stratford-by-Bow; Holy Trinity, Wimbledon; and Midgham and Brimpton, Berks. Roslyn Chapel and residentiary, Hampstead, was built from his designs in 1867.

BUILDING NEWS DESIGNING CLUB.

REVIEW OF DESIGNS FOR SEMI-DETACHED VILLAS.

IN this competition merit of planning is not so conspicuous as we anticipated. "S" in circle, which we are obliged to place first, does not happily solve the problem given. The plan is compact in the lobby and hall arrangement, though we do not like the cramped stairs, and certainly not the winders. The kitchen, too, is too small, measuring only 7ft. across at the entrance end, and there is no copper shown in scullery. The entrance would have been better if it had been placed in a cross passage, and the kitchen beyond it. We think the dining-room also is too small. On the upper floor the plan has more merit, and in the elevation the author has certainly given us a common-sense treatment for brick and tile, the bays being carried up as gables in the roof story. The overhung doorways are rather crushed in effect. The cubing is put at 61,432ft. at 6d. per foot = £1,600. "Omega" has decided merits. The hall, stairs, and kitchen, with its window placed rather askance in the inner angle, are well planned, and the area is well utilised; the external elevation is simple, with tiled gables, but withal there is little striking or original. The skewed window is certainly better than a right-angled one in such a position. The cube contents are 54,806ft. "Yesram" obviates some of the defects common to many; the main entrance is at the side, a 4ft. passage leading direct from front to back; the kitchen is too small, but has an angle window, the scullery being made a passage room to the back. No windows, except the staircase, look upon the adjacent property, but the winders to the stairs are objectionable, and elevation falls short. Why such small windows to the drawing-rooms and study? Cubing is 61,256ft. at 7d. = £1,785. The hollow walls are good points. In "Confido" the kitchen is cramped. The window facing a tradesmen's entrance lobby is clever though not desirable, and the scullery and copper are too confined. The staircase and lobby arrangement between kitchen and dining-room and the china closet is ingeniously contrived, and but for the two restricted outbuildings the design would have stood higher. Elevations are somewhat hackneyed. The cubing is well worked out at 73d. and at 5d., and the economy of space is obvious. "Motto J." sends a very pleasingly designed elevation in Queen Anne character, but living room and parlour are cramped, and the kitchen is much too small, being only 11ft. 6in. x 9ft. A side porch entrance is shown. The objection to overlooking by side windows has been met, however, and the plan has the merit of economy in the cubing, five bedrooms being provided. "Mechlin" has solved the difficulty of avoiding side windows, and has also obtained a tradesmen's entrance behind the main porch, both at the side; but the dining-room is too small, and the elevations are somewhat commonplace. Why not have thrown the porch into the hall, instead of notching it into the latter? We observe a germ of success in the plan, but it has been lost sight of. The cube contents of each house is put down as 23,411ft. priced at 8d., = £781 per house. "Mechlin" will find he has no headway on first landing, if we judge by his elevations. "R." in circle does not comply with the condition as to side lighting. His kitchen window faces directly upon the adjoining pair. With this exception the plan has some points of merit. The hall and entrance is placed next the party wall, the dining-room to the side of this, 16ft. 6in. x 13ft. 6in., while at the back is a good drawing-room, with a bay and a lobby entrance to kitchen, with a serving hatchway to dining-room. The elevation is designed in Queen Anne style, somewhat rural in feeling. Cube contents 61,182, at 6d. "Frappe Fort" sends a vigorously-drawn perspective with some heavy chimney caps, but the ground plan ignores the condition about avoiding overlooking windows, the kitchen having one facing laterally. There is a good dining-room, and some compact planning in the lobby and outbuildings—another merit like that of "R." already noticed, is that the offices do not extend behind, and form a long range to obstruct the light and view of back windows.

The fault of "North West," as of many others, is the crowding of the hall, and the window to kitchen being placed inconveniently close to that of the dining-room. The scullery is made the back entrance, the bedrooms are conveniently planned. We do not like the elevations nor the high-shouldered appearance of the gabled sides. The cubing is taken at 7d. for the main part and 4d. for the subordinate. Among ingenious attempts to avoid side lights, we may mention "D." in triangle, who places his kitchen next the party wall, but no side passage-way is allowed, and the whole 30ft. half frontage is taken up so that the windows shown of pantry and larder are useless. "En Avant" also occupies the entire frontage, and thus places himself out of the field. "S. C. M." shows a skylight to light kitchen, which is, however, too small, as is also the scullery. The narrow stairs and winders are objectionable, but the author is on the right scent. "Fritz" has boldly departed from the stereotyped disposition of rooms, and if he had shown a better stair and larger dining-room his plan would have at least the merit of originality. He puts the kitchen close to the party-wall of the pair and by the side of dining-room. "Lbs." avoids back offices entirely, places his two sitting-rooms in front, and lights his larder and china-closet by a central court common to the pair. The plan has some merit, though the details are poorly worked out. "Franc Tireur" is an ordinary arrangement, the kitchen window facing towards the yard. Elevation has some redeeming features, at least in front. Star in circle does not meet the conditions of competition, though there are one or two good points in plan. We cannot admire the elevation, with the uncomfortably close bay windows. "Spero Meliora." The crooked office wings are not desirable, and the remedy is worse than the evil. The drawings are carefully made. The author of "Curiose" falls into the common error of cramping the kitchen, while the china-closet opening out of entrance vestibule is surely wanting in convenience. "Tam O'Shanter" transposes the usual position of parlour and kitchen, the latter being placed next party-wall; the plan is certainly more compact than many others; there is a useful serving lobby, and the sculleries outside are back to back. The elevation is below the mark. The plan of "J. S." is an economical though somewhat awkward attempt to solve the question, and the kitchen after all has a side light. The best part of the design is the elevation, which is cleverly broken and simply treated. The cubing is at 8d. and 4½d. "K" in circle fails to meet the condition; the scullery entrance facing side passage is also objectionable, and would be tempting to a gossiping servant. "Semper Spiro Spero" has little to recommend the plan, and the stairs are objectionably awkward to get furniture up—a point many others are equally faulty in. "Namor's" arrangement is not happy, though it avoids a long back office wing. "Montague" places his drawing-room on the first floor, and his kitchen and scullery are side by side below, but the poor entrance and awkward deep bay windows are defects. "Try" does not attempt any new arrangement, but his kitchen wings are obtrusive and unsightly, and spoil the garden view from the dining-room. "Cabul" is better, and his details are good. "Heval." A plan avoiding back projections, but defective in lighting and detail. "C" in triangles has an economical ground plan, but the stairs, kitchen, and dining-room are cramped. "Omnia Vincit Labor" is wasteful in passages and ill-lighted. We have only space to further enumerate in order of their merit the following:—"Octagon," "Anchor," "East Anglican," "Such a Dog," "Maltese Cross," "Ich Dien," "Amateur," "Pat," "Signum," "M in Leaves," "B. M. W.," "C. W. D.," "E" in triangles, "Ogmore," and "Peter;" the first three or four of which possess points of merit in plan. In reviewing the designs we have noted that the larger number fail in adhering to the customary plan of semi-detached villas; others have simply changed the position of windows, while a few only have boldly tried to meet the difficulty by doing away with the usual office wings and disposing the offices anew—notably "Confido," "Frappe Fort," "R" in circle, "Lbs.," and a few others. A side passage way

is useful, but its chief use is to replenish the coal cellar. "S" in circle provides for this purpose only, but others have shown a passage way through. We think a side or recessed entrance a great point, as in the first three plans, and a servants' entrance may be well made through the scullery or a lobby between kitchen and hall. No plan, however, we have received has successfully met the condition proposed. The dining-room, hall, or kitchen, has in most cases suffered by the attempt, and few of the authors have availed themselves of a middle area for lighting a portion with any success. The details received are not equal to the occasion. Those of "Cabul" and "Frappe Fort" are the best, after which "Try" may be placed. "Spero Meliora" shows lack of experience, or he would never have designed such a wooden bracket as he has to his doorway. His brick architrave also is much too wide and out of proportion, and his gates and posts are too full of cross boarding and stop chamfers. Details by "Such a Dog" are wanting in knowledge of mouldings and precision of drawing. In concluding this review it must not be supposed that we have entered minutely into the construction and detail of the various designs submitted to us. If we were to do so our task would be an endless one for ourselves and wearisome to the patience of our readers, while the main object of our criticism would be lost—namely, the inculcation of sound principles of general planning and good design.

SUGGESTIONS RELATING TO PLANS, MAIN DRAINAGE, AND WATER SUPPLY.

THE Local Government Board have just published, in official blue-book form, some information that should have been made known years ago; but as the old adage says, "It is better late than never," we welcome the revised pamphlet before us of "Suggestions," by Mr. Robert Rawlinson, C.B., C.E. These include information relative to maps and plans of districts to be submitted when sanction is required for loans and other purposes of the Public Health Act, as well as information respecting works of main sewerage and water supply. The appendices are quite as useful to the town surveyor. They furnish suggestions as to contracts and specifications, instructions as to applications, schedules of prices for well-sinking and boring, table of prime cost of machines for raising water, regulations for house fittings for water supply, specimens of plans, &c. We will here briefly give the gist of the more useful suggestions relating to main drainage. As to boundary maps it is stated "in cases in which a local government district or a special drainage district is proposed to be formed, a map should be submitted, accompanied by a written description of the proposed boundary clearly defined." The area in acres has to be given with the population and number of houses. The rate of increase of population, and a duplicate of the map on tracing cloth, are also required. Ward maps should have the main boundary distinctly defined thereon, and the proposed division into wards, taking advantage for such boundaries of brooks, roads, foot-walks, streets, or fences, such lines to be defined by margins of colour, with the names, areas, populations, and rateable values of each ward. Upon application being made for loans, plans (or tracings), sections, detailed estimates, and specification are necessary, accompanied by information as to population at the two last periods of taking the census, the rateable value, and the amount of outstanding loans. Lines of main sewers and drains should have the cross sectional dimensions and the gradients marked upon them, the dimensions of water and gas-pipes being also shown. A specimen plan is given which will be found useful. It shows red lines for sewers, small circles of red for manholes, ventilating or flushing chambers, brown lines for pipe sewers, either double or single, according to size, blue lines for iron pipes, and the flow of sewage is indicated by an arrow. It is stated that no general map should be submitted which is drawn to a scale of less than 6in. to the mile, except when the inch ordnance map is used. For showing sewerage or water works, or street improvements, maps should not be less than the ordnance scale of 1-2,500th. Detail plans are to be in a scale of

not less than 10ft. to a mile, the houses, bench marks, levels of streets and cellars, high and low tide level, &c., being shown; and 8ft. x 2ft. is suggested as a convenient size for sheets. A specimen of this plan is also given. Enlarged details of sewers, manholes, sluices, &c., are, to be not less than 8ft. to the inch, or to any larger scale. Engraved or lithographed diagrams are also accepted.

Referring to the suggestions some valuable points respecting main sewers are given. It is hinted they should be laid at "such depth as will effectively drain house basements, and, when practicable, not less than twice the full diameter of the sewer below basement or cellar floors, to prevent house drains from being back-watered. Drains from basement to sewer should have a clear fall of not less than 1 in 60, and should enter sewer by a junction specially provided for that purpose." Sewers and drains on sites liable to be flooded require to have outlets with valves, to prevent floods back-watering the sewers. Tidal flap valves are illustrated, also penstocks for sewers. Plate 18 shows a self-acting overflow valve hung on pivots, so hung as to close against flooding. Street surface ventilation, it is pointed out, cannot be provided below the surface flood level: they must therefore be ventilated above. No. 3 suggestion states, "Main sewers must not be of capacity to contain flood water of the area drained, as such flood water should be passed over the surface, or by special channels and drains." This condition seems to be desirable on the score of economy, though we believe that special flood-water drains are seldom thought of. In the laying-out of main sewers straight lines and true gradients are recommended, the chief changes of line and gradient being provided for by side entrances, manholes, and flushing arrangements. A section of manhole and ventilating shaft is given (Plate 4), the latter being independent and not so deep, with a coarse gravel bottom for draining, and a charcoal basket in a vertical opening between the two shafts. Another diagram exhibits a system of ventilation that has been found successful. It shows the usual manhole and shaft, with a close movable iron cover at the street level. Two charcoal baskets are placed across the shaft, through which the sewer gas percolates and becomes disinfected, above which it passes into a side ventilating chamber, and thence through a grating in the street. Any solid matter falling through can be removed by a slide at the lower end of chamber. Speaking of the duplicate system of sewerage, Mr. Rawlinson says it is seldom required, and existing road drains may be retained for storm waters. He states objections to the double system, but these have been answered before, and do not take into consideration the principle of making a separate drain the channel for an excess only of rain-water. A separate system, we assert, would not entail two sets of drains to the houses, as the house drains would be single as at present. House drains are recommended to be laid in concrete, and if the subsoil is porous the trench should be lined with clay puddle. For the jointing of pipes concrete or cement is suggested in preference to clay, though to the second material we have strong objections. At junctions and curves an extra fall to compensate for friction is advised, and when two sewers of unequal diameters join, the lesser sewer should have a fall into the larger equal to difference of the diameters. We have no space to recapitulate other suggestions, many of which are obvious and well known. We may mention, however, that house drains are recommended not to pass direct from sewers to the inside of houses, but they should end at an outside wall. Sinks and closets should be also against outer walls, and be discharged into ventilated traps. Down spouts are not to be used for ventilation as the heads may be near windows, so that the open soil pipe system cannot be enforced under this rather unnecessary rule. Side junctions are to be provided for house drains. Back drainage is recommended on the right-line system from manhole to manhole. On the question of sewers in hilly districts, Mr. Rawlinson recommends sewerage in zones, or by intercepting lines of sewers contouring the site, as they prevent gorging the low-level districts, and the rush of sewage down steep gradients, which in times of

heavy rain may burst the low-level sewers at the steep junctions. Steep sewers require to be better ventilated than flat ones to prevent dangerous accumulation of gas in the upper districts, and the arrangement already described of ventilated manholes is proposed, with "tumbling bays" between the two levels. Tide-locked sewers must be constructed so that the lower portion below the level of high water or land floods of a river should be cut off from the upper portions and be amply ventilated, and a section of an arrangement for a main outlet on seashore is given with a manhole ventilating chamber, a hinged flap valve to outlet sewer, also a flood-water overflow. We are glad to find trapping not advised in cases of offensive sewers, but additional openings for ventilation, and another good hint is that single ventilating tubes are useless. There should always be two—an inlet and outlet—or the single pipe should be divided by a diaphragm. A little more classification in the suggestions would have been desirable, as we find the same branches of the subject are repeated. In the chapter on "Water Supply," a few useful hints are given. Thus it is advised that cast-iron pipes should be coated inside and out with black varnish. Turned bored joints are said to be cheapest, but lead joints are safest. Specimens of tanks are given, and these may be of brick or concrete, made water-tight by clay-puddling the bottom, and concreted, the thickness of puddle being not less than 12in., and spread evenly over the whole surface of site. Into the part on "Sewage Disposal" we have no space to enter here, and as to the appendices we may profitably refer to them on another occasion. Mr. Rawlinson's "Suggestions," if they had been published years ago, would have saved many useless labours on the part of town surveyors, and expensive failures, but though it has appeared late in the day it will be found a useful guide to the profession.

The total depth of the artesian well being bored for the Vestry of Richmond, Surrey, is now 355ft.; the last 100ft. are sunk in the chalk, and the contractors are confident of obtaining sufficient water before reaching the maximum depth—415ft.—prescribed by the contract. Messrs. Ross and Mions are the engineers.

The Local Board of Civil Works, Wilts, have decided to apply to the Public Works Loan Commissioners for a loan of £5,000 for carrying out works of sewerage.

At Marlborough-street police-court, London, on Monday week John Clarke, clerk to a builder of Chapel-street, Mayfair, was sentenced to a month's imprisonment with hard labour, for stealing £3, given him by his employer to pay for advertisements in a newspaper.

A new stained glass window has been placed in the chancel of All Saints' Church, Hnningdon, during the past fortnight. It is in three lights, and represents the Lord's Supper. Our Lord, portrayed in the act of blessing the bread, occupies the centre light with six of the Apostles on either side. Through the window is seen a distant view of Jerusalem by night. The work was executed by Mr. W. H. Dixon, of London and Sheffield. All the chancel windows in this church have now been filled with stained glass.

The Wesleyan chapel at Redwick, near Bristol, was recently reopened after considerable alteration and improvement, carried out from the designs of Mr. Herbert J. Jones, of Bristol. A school for 60 children has been erected at the rear of the chapel. All the internal fittings in the latter building have been removed and replaced by a rostrum and open seats, all framed in pitch pine with white deal panels. The contractors were Messrs. Lewis and Edbrooke, of Bristol.

A stained glass window has been placed in the south transept of Hereford Cathedral to the memory of the Rev. John Goss, vicar of St. John Baptist, Hereford, and son of Sir Joseph Goss, organist of St. Paul's Cathedral.

At Ayot St. Peter's, Herts, a novel use of Rust's mosaic has been made in its application to the face of the new clock which has been given to the church. The centre is composed of gold colour scrolls upon an azure ground, and around this is a belt of circles of white, bearing the figures of the hours in black, and the spandrels are alternately dark blue and ruby. The work has been carried out from the designs of Mr. J. P. Seddon, who was also the architect of the church itself.

A new church is about to be built at Peel, Isle of Man, from the designs of Messrs. Charles Barry and Son, of Liverpool, and in counterpart of a church recently erected by them at Bolton.

Building Intelligence.

ABERFORD, NEAR LEEDS.—Alterations have been going on at the Catholic chapel of Aberford, and are now about approaching completion. The sanctuary has been re-decorated, new reredos to high altar, new Lady altar, new sanctuary fittings, which have been supplied from Birmingham. The nave has also been decorated, and new seats have been supplied, and a new porch and wind porch. The chapel had for some time been in want of repair, and Mr. M. W. Lewis, architect, Stonegate, York, was instructed to prepare designs, and the work has been carried out under his directions.

CARLISLE.—Messrs. J. A. Tomlinson and Co.'s Nelson-street Works, Denton Holme, Carlisle, are now completed. The machinery and fittings are also ready for starting to run. The loom shed is about 133ft. square, and contains 322 looms, and is so planned as to be easily extended. The warehouse block, measuring 184ft. x 34ft., and three stories high, is placed to the front, being somewhat ornate, and contains long rooms for beaming, warping, sizing, &c. The engines and boilers, chimney (100ft. high), mechanics' shops, twisting block, stables, &c., comprise a block of buildings on the right hand of loom shed. The work has been executed by Messrs. C. and J. Armstrong, contractors, at a cost of from £8,000 to £9,000, exclusive of land and machinery. The engines and boilers are by Messrs. Pratchitt Bros. Mr. John Allan has acted as clerk of the works, and the whole has been carried out under the superintendence and from the designs of Messrs. Hetherington and Oliver, architects, Carlisle.

CARLTON, NEAR NOTTINGHAM.—New board schools were opened on the 30th ult. They are in three departments, each having a main room 51ft. x 20ft., and two class-rooms 20ft. x 15ft., with porches, cloak-rooms, and lavatories. The rooms are 16ft. high to plate, roofs open, timbered with arched principals. The walls are boarded 5ft. high, with inch rustic boarding, stained and varnished. The schools are Gothic in character, and are built of copper-mould bricks, with Bath stone dressings. A bell turret forms a conspicuous feature. There is a master's house, with large board room, and also a caretaker's house. The schools are heated by hot water. The works have been executed by Messrs. William Key and Francis Cave, of Carlton, at a cost of £5,295, from the designs and under the superintendence of Mr. Robt. C. Clarke, architect, Nottingham.

ECCLESTON.—New schools and master's house have recently been erected at the cost of the Duke of Westminster, at Eccleston, Cheshire. The whole of the walls are of red sandstone, and the roofs are tiled. The windows in the school are of a Gothic character, with stone tracery, and are filled with ornamental lead glazing. The gables of the house and the upper part of the walls are of black and white timber framing, which gives it a distinctive Domestic character. The most striking feature outside is a lofty stone bell turret, which is carried up one angle of the school, and contains a circular stone staircase, and above, the bell. The principal gable of the school terminates in a canopied niche, which contains in sculpture the old legend of King Alfred teaching a child to read. Eccleston school is perhaps the handsomest and most complete of all the six schools upon which the Duke's liberality has lately been engaged in this neighbourhood. All these have been from the designs of Mr. John Douglas, architect, of Chester.

TRURO.—Last Friday a new Methodist chapel was opened in Kenwyn-street. It is in the Early English style, and is capable of seating about 326 persons—236 on the ground-floor and 90 in an end gallery. The pews have solid ends and reclining backs, and in place of a pulpit there is a rostrum of ornamental design. In consequence of the peculiar situation of the building the light at the sides is very limited, and a clerestory has had to be added. The light thus obtained pervades the whole building. The facade is faced with granite pillars. The architect is Mr. J. Williams, of Knightsbridge, and Victoria-chambers, Derby.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post-free 24d. Office: 31, Tavistock-street, Covent-garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.] All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted, some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

J. N. BLACKPOOL. (Mr. Riddell's "Artisan" is to be had in this country only of Mr. F. Ship, 9, Church-road, Homerton, London, E. Mr. Ship has written us that he expects a larger consignment of copies daily, and that when they arrive the book will be advertised.)

"BUILDING NEWS" DESIGNING CLUB.

J. H. D. Tunbridge Wells. (In reply to your application we are constantly being asked for the same information, and again reply that conditions of the club were published in the BUILDING NEWS of September 20 last, copies of which may still be had on application to the publisher.)—EAST ANGLIAN. (I. Yes, if they are deserv- ing. 2. Your suggestion may be considered. We think it would be an advantage to adopt such an arrangement in the case of the more diligent and able of competitors.)

Correspondence.

THE CHAPTER-HOUSE AT ST. PAUL'S CATHEDRAL.

To the Editor of the BUILDING NEWS.

SIR,—We have most of us read with immense pleasure and profit Mr. Edmund B. Ferrey's interesting work upon Old St. Paul's. An article has appeared recently in *Notes and Queries* relative to the chapter-house, from which an extract or two may be acceptable to your readers. The original chapter-house, according to the best authorities, stood west of the south transept, but the present one, as many may remember, is in St. Paul's Churchyard, north of the Cathedral. It is a red-brick building, designed by Sir Christopher Wren, and its erection was completed, according to the Fabric Rolls, in June, 1712—i.e., some two years after the completion of the new Cathedral itself.

The first chapter-house was undoubtedly destroyed with the rest of the Cathedral, and hence from 1666 till 1712 some other one was used. This is generally supposed to have been upon or near the site for the present one, for

frequent references are made during the period mentioned to the chapter-house on the north side of the yard. Indeed, in Mr. Crace's new work, "A Catalogue of Maps, Plans, and Views of London, Westminster, and Southwark," a view occurs of a prior one on that site, drawn by "J. Harriadel, and sculptured 1668." It was therein that, in James II.'s time, Dr. Johnson, chaplain to William, Earl Russell, was solemnly degraded by a trio of bishops.

The cost of the present chapter-house was a trifle over three thousand pounds, and these are the details of the account:—

	£	s.	d.
Thomas Scott, brickmaker	37	0	0
Richard Jennings, carpenter	776	9	2
Richard Jennings, for labour	20	0	0
Richard Billingham, bricklayer	483	15	1½
Richard Billingham, for labour	30	0	0
Edward Strong, mason	728	16	4
Edward Strong, for labour	138	6	6
Thomas Robison, smith	195	11	8½
Joseph Roberts, plumber	405	12	6
John Hopson, Esq., joiner	216	16	3
Total	3,092	7	7

Is it not probable that the "John Hopson, Esq.," alluded to may have been Sir Christopher's clerk of the works? About the commencement of the chapter-house's building Jennings, the carpenter, got into hot water with the dean and chapter, it seems, and proceedings were taken against him on March 20, 1710. The reason for this is explained in Elmes's "Memoirs of the Life and Works of Sir C. Wren." He states there that:—

Mr. Jennings left the work he was upon in the church (St. Paul's) unfinished, and of a sudden dismissed all the men, and then immediately employed such of them as would comply with him in the work of the chapter-house.

Here are some further details concerning the price of materials and labour:—

Place bricks, 14s. per thousand.
Rubble bricks, 30s. per thousand.
Grey stocks, 20s. per thousand.
Carpenters erecting scaffolding, 2s. 6d. a day.
Bricklayers, 2s. 6d. a day.
Masons, 2s. 6d. a day.
Masons' labourers, 1s. 6d. a day.
900ft. of stone sawn for the job at a cost of 6d. per foot.

In the present unsettled state of the labour market these latter prices, throwing light as they do upon the cost of material and labour one hundred and sixty odd years ago, is of exceptional interest.—I am, &c.,

Exeter, Dec. 30, 1878. HARRY HEMS.

CUSTOMARY PERCENTAGE.

SIR,—I am much obliged for the result of the experience of your correspondents confirming the quantity surveyor's commission charges, about which I solicited their opinion.

"Every labourer is worthy his hire," and I am one of the last that would with parsimonious hand dole out a mere pittance for services rendered; apart from the innate feeling prompting the action, my experience teaches me the advantages that accrue from remunerating according to deserts—pay a man well, and you are more likely to obtain a just return for his wage.

I say, then, if quantity surveyors are indispensable adjuncts to contracting, let them be recognised as such, and paid commissions in proportion to their utility and essentiality; it is not so much the amount of percentage they claim as the sinister way in which they are made (by some of the profession) that I object to. If they are correct, and surveyors can prove their entitlement to them—be they 2 or 5 per cent.—why should they be disguised? Why should not those charges appear on the face of the accounts, so that clients may know that such service being needed, they have full value for their money? By the system now practised their eyes are blinded to the fact.

The case to which I alluded is—must be, I am sure—an exceptional one, and when I tell your correspondents (one of whom speaks of their fees being "hardly earned enough"), they will think so, too—that a clerk's week's work earned for the principal £230 on "omissions;" that five or six weeks' application secured him another £1,000, for measuring and making out the accounts; that a further sum of £700 was derived from making out the day-work

accounts, the whole being the produce of one contract, irrespective of commission on "bills of quantities."

One of your correspondents considers it of primary consequence that the "client's interest, in any case, should be protected." Whether such inference may be drawn from the architect sanctioning his employers being saddled with such augmented cost of their work, as the above shows, I will leave your readers to decide.—I am, &c., A. CONSTANT READER.

BELHAVEN CHURCH, GLASGOW.

SIR,—I am anxious to take the first opportunity of calling your attention to a strong case of likeness between two designs.

If you will refer first to the "Belhaven Church, Glasgow," Campbell Douglas, E. Sellars, architects, in your last number, dated Dec. 27th, 1878, and then turn to your issue of January 10th, 1879, illustrating "The English Church at Lyons," by R. Norman Shaw, A.R.A., no doubt you will be struck, on comparison, by the similarities which have prompted me to write to you. To wit: general grouping, flat-buttressed gable-end lancet windows, parapet above, low arcade below, and still lower plain wall surface. See the similarity between the start of the saddle stones for the gable crosses, and then follow the coping stones of the minor gables down to their bases. Is it not curious that there they die in both designs on to the outer side of a gabled buttress head? If Mr. Shaw ever had a peculiarity in design this feature certainly is his.

I could go much further, and point out other coincidences (compare in passing the entrance doors, above them the deep horizontal coping, and higher still the transept), but I think enough has been placed side by side to show you that, although Belhaven, Glasgow, is a long way distant from Lyons, there is a flower common to both, from which the honey of the "motifs" of these designs has been extracted.

I use "motif" advisedly, as in the different parts, where likenesses have been detected, distinctions, alterations, and changes of detail have been introduced.

There is also some similarity in the etching of the drawings—for instance, the lead-work of windows. While on the subject of drawing how comes it that in the Belhaven drawing the room on the extreme right of the view is shown polygonal, and in the plan is semi-circular? I must say that I cannot put in any claim here of similarity for Mr. Shaw. In conclusion I should like to know what the gable wall of the transept stands on. I see nothing in plan which would carry it in true perspective.—I am, &c., WYKEHAM.
December 31st.

ELECTIONS AT THE A. A.

SIR,—Your correspondent, Mr. Leaning, does not, I think, quite fairly indicate the question at issue in connection with the recent discussion. It is not so much "whether the plan of voting by ballot should be retained or not," as whether the elections should be a sensible reality or a farce—we might perhaps say, whether any form of election at all should be retained or not. It is surely somewhat late in the day to bring forward the old oft-explored objections to the ballot, and as they have been answered so many times by those who struggled for its introduction into the political world, I need not attempt to combat them in your columns.

The very existence of any form of election implies that the power of rejection as well as of acceptance is possessed by the electors; but if this power must never be exercised, it practically ceases to exist, and the form of expressing acceptance may as well be dispensed with altogether.

Something further is also surely implied in a form of election—viz., that the electors are individually capable of deciding upon the merits or qualifications of candidates, and Mr. Leaning will kindly tell us that a pupil who has been only, say, a month in an architect's office, and who has perhaps never previously attended the Association meetings is entirely competent to decide whether certain other students do or do not comply with the necessary conditions. If we are told that no candi-

date should be brought forward without the special sanction of the committee, thereby insuring, to a certain extent, his fitness, that is exactly what we have argued for; but if those who object to the ballot were consistent, they would think any form of election, after the approval of the committee, to be unnecessary. Indeed, it has been stated that to reject a candidate who had the committee's recommendation would be to indicate a want of confidence in their judgment, and might lead to their resignation. If so, why not do away with the form of election by the general body of members? It would have become an absurdity and waste of time. However, it would, we think, be desirable that in addition to a careful scrutiny by the committee, all those members who might be reckoned among the senior or more prominent ones, should have the power of acceptance or rejection, and the society is too well established to be frightened at the bugbear of "class prejudice." The two classes of members do actually exist at the present time, though without a distinct line of separation, and it is idle to talk of "equality" between a pupil of a month's and a practitioner of forty years' standing. The argument about subscription is equally beside the mark. The junior members get a far larger share (if not all) of the advantages than the senior members, who, in addition to their subscription, give their time and assistance in many ways towards the studies of younger men; but we have not heard of the seniors claiming exemption from the annual payment on the ground that they get nothing in return. The greatest possible advantage will result from the full discussion of the whole subject, but, in the first instance, it should be rather upon broad general principles than minute points of detail, which may well be left to the consideration of the committee.—I am, &c.,

WILLIAM SCOTT.

The foundation stone of new works of sewerage were publicly laid last week at Bygrave-mead, Miteham, Surrey. The works are being carried out for the Croydon rural sanitary authority, by Mr. Baldwin Latham, C.E., and are expected to cost about £50,000.

It is about five years since Bangor Cathedral was reopened after the restoration of the choir and transepts at a cost of more than £20,000. The Dean and Chapter are now desirous of making a fresh effort to restore the nave and side aisles, the chapter-house, and cathedral yard, works which it is hoped to effect for £6,000, leaving the erection of the tower to a future date. The concrete floor of the nave and side aisles, which was only laid down for temporary use in 1873, is already beginning to give way.

Within the last few days the London and North-Western Railway Company have sapped up the only portion left of Northampton Castle. The local engineer, Mr. Trench, has kindly suspended the removal by gunpowder of these massive remains until Sir Henry Dryden has taken drawings and plans of the doomed piece of masonry. Meantime the people of the county are sending an earnest memorial to the chairman and directors of the company, to request them, if possible, to save this last relic of a building so rich in historical associations.

The Church of St. Mary-at-Hill, Eastcheap, has been scheduled by the Inner Circle line in the scheme receiving Parliamentary sanction, though they do not propose to go nearer to the site than 75ft., the widening of the thoroughfare also at this point not coming within 15ft. The rector will oppose the scheme.

The chancel of the parish church of Nether Swell was enriched on Christmas Eve by the insertion of stained glass in a double lancet window on the north side. The subjects are the Agony and Betrayal of the Saviour. The work has been executed by Messrs. Clayton and Bell, of London.

Mr. John Chapple has been appointed consulting surveyor to the Dean and Chapter of Rochester—an office which he will hold in addition to that of clerk of works at the Cathedral of St. Alban's, where the works for the past eight years have been under his supervision.

At a special meeting of the Corporation of Taunton, held last week, it was resolved to invite the Royal Archaeological Institute to hold its meeting for 1879 in Taunton. A reply has since been received from the institute accepting the invitation, and a local committee is being organised to make all arrangements for the autumnal congress.

Mr. Martin Humphrey, builder of Helmdon, near Bantry, was killed while crossing the Great Western Railway near his home on Christmas-eve.

Intercommunication.

QUESTIONS.

[5624.]—**Tiled Roof.**—A builder who is putting on a tiled roof has it specified that the tiles be laid to a 2½ in. lap. Which is usual, to measure lap from pin-hole or from head of tile? The experience of some of your readers on this point would oblige.—ST.

[5625.]—**Rendering Wood Incombustible.**—Is any process known whereby wood can be made incombustible? The process, of course, must be such that its effect will last, and not be so expensive as to prohibit its adoption when the wood so treated is to be used in large quantities.—W. X.

[5626.]—**Hollow Walls.**—In building a 14 in. wall hollow may I ask it is considered better to place the 9 in. or the 4½ in. thickness on the outside of the hollow space? Will tile hanging on the outside of a 4½ in. wall keep the upper story of a dwelling-house dry? In the case of the half-timbered work, of which there is now such a revival, is it considered that a 4½ in. brick flat between the timbers, if rendered in cement on the outside and fastened on the inside, will keep out the damp?—W. R.

[5627.]—**Fir Timber.**—Can any of your many readers experienced in the timber trade define the meaning of the term "fir" in a bill of quantities where the specification preceding same distinctly states that all timber, unless otherwise specified, to be "best quality Baltic red wood," and in giving quantities of rafters, &c.—say 100ft. lineal, 4½ in. x 3 in. "rough fir" rafters—what sort of timber would it imply? Could the term be construed to mean spruce fir? Any information would oblige.—TIMBER.

[5628.]—**Marble Floor.**—I have been asked to give an opinion respecting the decay of a marble floor. Perhaps some reader will kindly help me. The floor has been laid about two years, and has now the appearance of fretting away and getting shaly in places—more particularly in the black, dark green, and red. The Sielhan jasper used is worst of all. The floor is laid on, I believe, a bed of Portland cement, and has been regularly cleaned with turpentine, as directed by those who put it down. Has this anything to do with the decay? Some of the marbles are quite untouched; in others it seems as if the stopping used by the polishers had come out.—A. K.

REPLIES.

[5616.]—**Expiration of Articles.**—Nothing further needed or usual beyond an endorsement—"Duly served and to my satisfaction. Signed 'A. B.'"—B.

[5618.]—**Etchings.**—The best frame for etchings and prints is one made of oak, flat on face, the edges being chamfered or moulded, and a flat gilt margin inside. Most of the best etchings and monochrome drawings—such as those of the old masters in Grosvenor Gallery—are so framed.—G. H. G.

[5619.]—**Surveyor's Practice.**—"Surveyor's" valuation of the matter he names would, for all practical purposes, be utterly valueless, and of no weight whatever; except in case of a decision as arbitrator, where he would probably adjudge on evidence laid before him. It would scarcely pay to take out appraiser's licences for purposes of this kind; his valuation might be challenged for absence of the licence, but there would be so many other valid objections raised that he could afford to risk this one.—B.

[5620.]—**Levels.**—In setting out depths of drains the best plan is to fix plugs or as they are called "sight-rails," along the centre line of road, and to mark the depth of invert on them at the several points. The sight-rails may be fixed to represent the run or inclination of the sewers, and thus it is easy to determine the several depths below surface of ground. Care is required that these bench marks are not liable to disturbance on account of the excavations or from settlement of ground, and many sewers and drains have suffered in correctness from this cause. On this account they should be firmly fixed in immovable ground.—G. H. G.

[5621.]—**Strength of Timber.**—The question of "J. A. A." is one that has been answered so many times in the BUILDING NEWS that it would be better to refer to back numbers than to reply *de novo*. As it happens, however, the question appears in the same number as the rule. I refer "J. A. A." to the "Commonplace Column," page 708, where he will find rules that will enable him to find the depth of girders, binders, and joists. A table of scantlings is also given.—A SUBSCRIBER FOR YEARS.

[5623.]—**Compensation for Use of Party Wall.**—It would appear from the railway company having flagged close to the party wall they have forfeited their right to the strip of ground. If the company do not set up their right within a reasonable period their interest will cease. It would be unsafe, however, to build shops till such a period has established year right.—A SURVEYOR.

Our Office Table.

THE certificates gained by students at the Crystal Palace School of Practical Engineering were distributed on Saturday week by Mr. Harrison Hayter, Mem. Council Institute, C.E., who, in addressing students and visitors, gave it as his opinion that during the present distress engineers were fully employed and better off than the members of most professions. He advocated the system of pupilage, and the necessity of becoming acquainted with practical engineering before going into the civil engineering department. Too many went from a grammar school to a university before entering an engineer's office, and then were highly educated and too old to undergo the drudgery and dirty work necessary for practically understanding the mechanics of their profession. As to the future of engineering he thought railway works were overstocked, but amongst the branches which were not so well filled he cited dock, harbour, water, and gas works, drainage, irrigation, and "electrical engineering." He urged those contemplating entering the profession to take up some speciality—one or two subjects at the most, and not to attempt to grasp all engineering subjects. The essentials of success in the profession he epitomised as indomitable perseverance, honesty of purpose, a knowledge of "how to deal with men," and, lastly, a thorough knowledge of the profession.

THE frost of last week seriously damaged one of the main pillars of the High-level Bridge, Newcastle-on-Tyne. These immense supports are square tubes of more than a foot in thickness, and have iron rods 3 or 4 inches in diameter running down the centre. During one of the recent thaws the water seems to have filtered into the top of the pillar from the level of the railway, and to have collected at the base, the frost afterwards transforming it into a block of ice, which up till Tuesday was about a foot in depth and of the full width of the interior of the column, which had moulded it into its own shape. The expansion resulting from the changeable state of the weather gave such tremendous force to the ice that it burst away the pillar from near the roadway of the bridge to about 3ft. in height. Immediately the event occurred the engineers of the North-Eastern Railway Company inspected the damage, and a temporary wooden support was erected by the side of the original pillar until it could be repaired or replaced.

THE construction of the Lewes and East Grinstead Railway is being actively proceeded with in the neighbourhood of West Hoathly, particularly the tunnel under the Sharp Thorn Ridge, which is about half a mile in length. Five shafts have been sunk for the purpose of expediting the work underground, and at each shaft is an engine for hoisting and lowering workmen and materials. The preliminary drift-way is almost completed from one end to the other. The tunnel passes through a very hard dark blue clay, of the Wealden series. The end is expected to be completed in about two years. Mr. John Wolfe Barry, M.I.C.E., of Westminster, is the company's engineer; Mr. John Robinson, M.I.C.E., of Newick, the executive engineer; and Mr. Firbank, the contractor.

THE new Act to consolidate and amend the law relating to factories and workshops came into force on Wednesday. It is a long Act, containing some 107 sections and several schedules, with numerous regulations to carry out the new law. It is divided into four parts. The first has reference to the general law relating to factories and workshops, including the safety of machinery, the employment of children, and the meal-times appointed. The second part relates to special provisions of particular cases, and the third part to administration, penalties, and legal proceedings under the Act. The fourth part has reference to definitions, and to the repeal of nearly 20 statutes and parts by the new law. There are various provisions as to holidays and the employment of young children. Considerable powers are conferred on inspectors to enter all factories. A notice in the *London Gazette* of Tuesday night defines the words "attendance at school" in the 23rd section of the Act as meaning the

attendance of a child at a morning or afternoon meeting of a school during not less than two hours of instruction in secular subjects.

THE Paris correspondent of the *American Architect*, in the course of some interesting notes on the buildings at the late Paris Exhibition, in the Christmas number of that journal, makes the following remark upon the house erected from the designs of Mr. T. E. Collcutt, F.R.I.B.A., in the Rue Internationale. He says:—"I happened to see a perspective drawing of this house front at the Academy Exhibition* in London. The drawing was prettier than the house, and the house had more quaintness and character than the drawing. The drawing seemed made by one who was rather an artist than an architect; the house was made by one who seemed rather an architect than an artist." We question the orthodoxy of this attempt at defining the difference between an artist and an architect. We have certainly never seen a perspective drawing by Mr. Collcutt—so cannot say what he may be able to do in the way of pictures, but his designs are certainly the work of an artist. Few architects are able to make good perspectives, but some of them, at any rate, are artists nevertheless. The same journal says: "Most of our readers have some familiarity with the name of Sir Edmund Beckett, the thorn in the side of our profession in England. It is not a great while since the Royal Institute of British Architects undertook to weave their thorn into a crown by electing Sir Edmund to their new grade of Hon. Associate. This might have seemed to outsiders an indication of change of heart on his part, but it was said to be a simple act of propitiation. It would appear that, as propitiatory acts are apt to be, this was fruitless, and the thorn continues to grow inward." We believe it is generally thought that the R.I.B.A. are afraid of this "active tormentor of architects," and we are glad to see that some of the better known members have spoken out, as in our correspondence columns to-day, in such a way as the Institute shrank from doing.

To-day tenders will be received for a church (St. Michael and All Angels) possessing more than usual uniqueness of character, about to be built on the Bedford Park Estate, Turnham-green, Mr. R. Norman Shaw, R.A., being the architect. The design is certainly one of the most piquant we have seen for a long time and puts us in mind of that quaint mixture of Late Gothic and Renaissance, which is to be seen in a few towns and out-of-the-way places, erected in the time of the Jameses. The library of Lambeth Palace is of such a character, but the work of Mr. Shaw does not contain anything the most conscientious Gothickist could object to, though there is a quaintly hybrid feeling in the gable of west elevation, the pedimented caps to the buttresses, the large circular brick carved window and the curious bracketed porch. Essentially picturesque also is the cupola.

* Published in the *BUILDING NEWS*, May 10, 1878.

between nave and chancel, springing from a plain level-tiled roof, and the three clerestory windows treated as dormers, with a balcony over aisle roof. The aisle and chancel windows are four-light, square-headed, Gothic in detail, but the east window is a pleasing variation from Late Gothic. The plan sections show a nave and two wide aisles, a deep chancel organ chamber and vestry, the nave being divided into four bays by obtusely-pointed arches. The roof, with its elliptical ribs and radiating struts over aisles is quite original in its framing, and though we take exception to one or two points, the design is highly interesting. We note the sanctuary is to be hung with stamped leather, and the woodwork throughout painted sage-green. We shall shortly publish some drawings of the church.

WATER SUPPLY AND SANITARY MATTERS.

CROYDON.—The rural sanitary authority of the Croydon Union have just commenced drainage works for the Mitcham, Merton, Morden, Wallington, and Beddington district, which will involve the construction of 36 miles of sewers. The land for the outfall works, which are situated at Bygrove Mead, partly in the parish of Mitcham, and partly in Wimbledon, has been purchased at a cost of £11,300, and the engineering and superintendence will bring the total outlay up to £200,000. Mr. Baldwin Latham is the engineer, and the contractors for the construction of the works are Messrs. B. Cooke and Co., Battersea.

LANCASTER'S KILNS

FOR BURNING BRICKS, &c.,

(Patented in England, France, and Germany),

Effect a Great Saving in Charging and Discharging, and
50 per cent. of Fuel.

Apply to ROBERT LANCASTER, Leeds Brickmaking Company
(Limited), Armley, Leeds.

LEGAL INTELLIGENCE.

NONCOMPLETION OF CONTRACT.—At Bridlington County Court, last week, the case of *Pickering v. Armstrong and Newton* was heard before Mr. Bedwell, judge. It was a claim of £10 for non-completion of contract. Defendants had entered into an agreement to do the brickwork required in the erection of five new houses in Medina-avenue, Bridlington. They neglected to complete the work, and plaintiff had to get other workmen to do it. The charges put in were the actual amounts paid for such completion. For the defence a set off of extras was put in, and it was contended that the specifications had been altered by erasures and interlineations since they signed the contract. Verdict for plaintiff of £4 and costs.

HELLIWELL'S Patent New System of AIR AND WATER-TIGHT IMPERISHABLE GLAZING.

All woodwork is covered, and no outside painting is required. Old Roofs re-glazed. Any one can repair or take in pieces.

EXTRACTS FROM THE FOLLOWING PAPERS:—

"It is suitable for Railway Stations, Mills, Weaving Sheds, &c., but is specially applicable to Conservatories, Plant Houses, and Orchard Houses, and we should be very much inclined to try the system. It is certainly worth looking to."—*The Builder*.

"And will, in our opinion, supersede any other similar system before the public."—*Building News*.

"It seems to meet the end in view more nearly than anything we have seen yet."—*The Field*.

"The patent has given high satisfaction to every one using it."—*The Christian Union*.

"Convincingly proves the new Glazing System to be worthy the attention of readers of the *Keystone*."—*The Keystone*.

For Estimates, Drawings, or particulars, apply to the Patentee,

T. W. HELLIWELL,

BRIGHOUSE, YORKSHIRE; OR,
19, PARLIAMENT STREET, LONDON.

CHIPS.

A new police station and lock-up is about to be built at Long Eaton for the Derbyshire magistrates, from the designs of Mr. J. Somes Story, county surveyor; eleven tenders have been sent in for the work.

The Baptist chapel at Ripley, Derbyshire, has been reopened after alteration, from the designs of Mr. R. Argile, jun., effected at a cost of £200. Mr. W. Clarke, of Ripley, was the builder, and Mr. W. Roe the decorator.

The Chesterfield rural sanitary authority having received the sanction of the Local Government Board for a loan of £25,000 for works of water supply for Coal Aston, Dronfield, Eckington, Holmesfield, Killamarsh, Unstone, and contributory places, have authorised their engineer, Mr. Firth, to commence operations as early as practicable.

A stained glass window has just been placed in the south aisle of St. Edmund's Church, Salisbury. The subject is "Our Lord Purging the Temple."

New schools have been built at Prittlewell for the Southend-on-Sea School Board. Mr. Scott was the contractor.

The Town Commissioners of Weston-super-Mare received on Thursday week the deed of conveyance of the Local Water Works Company. The sum to be paid by the ratepayers to the company for the transfer is £65,000.

A series of street tramways were opened at Newcastle-on-Tyne on Monday week. They have been constructed for the Corporation at a cost of £30,000.

An infectious diseases hospital has just been completed for the Eastbourne Board of Guardians, from the designs of their architect, Mr. G. A. Wallis.

CHAPPUIS' PATENTS

FOR

REFLECTING LIGHT.—DAYLIGHT REFLECTORS

OF EVERY DESCRIPTION, ALSO

ARTIFICIAL LIGHT REFLECTORS.

P. E. CHAPPUIS, Patentee.

Factory, 69, Fleet-street, London, E.C.

N.B.—DIAGRAMS AND PROSPECTUSES ON APPLICATION.

At a special meeting of the shareholders in the Dorking Water Company, the requisite sanction was given to an application to the Board of Trade, for a provisional order to enable the company to raise £10,000 additional capital to extend their works and obtain a new supply of water. The company's present supply only provides for about a third of the town, but it is proposed to obtain water by gravitation from the hills on the south-west of the town, and to furnish every house in Dorking with water.

Extensive improvements, carried out at a cost of £40,000, have just been completed at the London Bridge Terminus of the London, Brighton and South Coast Railway. The platforms have been lengthened into the "yard," the signalling apparatus has been concentrated into one improved house in the centre, in which are fixed 280 levers, the point arrangements have been remodelled, and the lamp-room has been removed from the end of the platforms to the arches beneath. Great difficulty has been encountered in making these changes, as not fewer than 500 trains pass in and out of the terminus every week-day, each of which has to cross over, not only from the down to the up sides, but also across at least one line of the second set of rails laid down both on the main and South London lines.

A fine arts loan exhibition was opened at Cheltenham yesterday.

A special meeting of Harwich Town Council was held a fortnight since, to consider the old and vexed question of sewerage, and, after a long discussion, it was decided by 10 votes to 2 that the scheme should be adopted. It was therefore decided to apply for permission to borrow £10,000 of the Public Works Loan Commissioners to carry out the same. Messrs. Russ and Minns, of Westminster, are the engineers.

The parish church of St. Peter, Matlack, Norfolk, was reopened on Sunday week, after restoration from the designs of Mr. Chapman, of Hanworth. The entire woodwork of the nave and aisles' roofs has been restored, but the lead has been removed and replaced by slates.

The contractor for the Auxiliary Water Works at Heanor, Mr. Horsfield, of Kimberley, has had his contract to sink at £9 per yard annulled. The works at the shaft, which is 120ft. deep, and has already cost about £500, are at a complete standstill owing to the influx of subsoil water.

Foundation and corner stones of new Primitive Methodist schools were laid in Sutherland-road, Gateshead, on Thursday week. The school will accommodate 400 children, and will cover an area of 41ft. 9in. by 34ft. 4in., besides vestries and heating chamber. Mr. Thomas Southern, of South Shields, is the architect, and Mr. Thomas H. Hutchinson, of Gateshead, is the builder. The cost has been £900.

Salem Chapel, Leeds, after being closed many weeks for extensive alterations, repainting, and decoration, was reopened on Monday. The work has been under the superintendence of Mr. Archibald Neill, architect, Cookridge-street, Leeds.

Eppe's Cocoa.—GRAVEYLAND COMFORTING.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected cocoa, Mr. Eppe has provided our breakfast tables with a delicately-flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Chief Service Gazette*.—Sold only in packets, labelled—"JAMES EPPE & CO., Homoeopathic Chemists, London."—[ADVT.]

WHITLAND ABBEY GREEN SLATES

These SLATES are of a grey-green tint, are stout, and made in all sizes. A large stock available for immediate delivery. For further particulars (with a list of important buildings covered) apply to the MANAGER, Clynderwen, R.S.O., Carmarthenshire.—[ADVT.]

Trade News.

WAGES MOVEMENT.

BURNLEY.—The master joiners of Burnley have given their men notice that after February 1st their wages will be reduced from 7d. to 7d. per hour, and their working time lengthened from 52 to 54 hours per week.

LEEDS.—The master builders of Leeds have given notice of a reduction of wages. The masons' and joiners' wages are to be reduced 1d. per hour, and a proportionate reduction is to be made in the other branches of the trade.

WOLVERHAMPTON.—On Saturday week the whole of the associated builders in Wolverhampton gave their men notice of a reduction of 1d. per hour all round, to take effect from January 18.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

HIGH-CLASS VARNISHES.

READE BROTHERS, Tower Varnish Works, Wolverhampton, respectfully invite attention to their Varnishes for House Painters, Decorators, and Builders, which will be found of uniform excellence, and for elasticity, lustre, and durability all that can be desired. They would direct special attention to their Extra Hard-Drying Varnishes for church seats, and seats of schools and public buildings, which for hard-drying, brilliancy, and wear are unsurpassed.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of FEVERS, BILIOUSNESS, SMALL-POX, SKIN DISEASES, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—[ADVT.]

Holloway's Ointment and Pills.—All ulcerations, sores, abscesses, bad legs, and skin diseases are best treated by these medicaments. The ointment eradicates all noxious taints, and makes every symptom assume a milder form, and this desirable result is made doubly certain by the purifying, regulating, and alterative power of the Pills.

THE BUILDING NEWS.

LONDON, FRIDAY, JANUARY 10, 1879.

ROYAL ACADEMY EXHIBITION OF WORKS BY THE OLD MASTERS.

THE old masters are just now represented in two of our leading art institutions with a completeness leaving nothing to be desired. At Burlington House an abundant feast was opened to the public last week; and the visitor—if he cares also to inspect the drawings and water-colours at the Grosvenor Gallery previously noticed by us—may obtain a very comprehensive view of the essential characteristics of the leading schools of painting, especially the Italian, German, Dutch, Flemish, and English. The works of the Caracci, Parmigiano, and Domenichino are numerous, but those giants of art, Raphael, Leonardo da Vinci, Michael Angelo, and Hans Holbein, are conspicuous at Burlington House. Portraiture takes up a large portion of the wall space, and we pass some excellent portraits in the first gallery by J. Hopper, R.A., Sir Thomas Lawrence, Sir Joshua Reynolds, George Romney, Hogarth, and Gainsborough. The portrait of Charles James Fox by Sir Joshua Reynolds (17), lent by the Earl of Leicester, is an exceedingly fine painting, possessing the freedom, vigour of handling, and colour of that illustrious master. It is half-length, showing the great statesman with a paper on a table entitled, "A Bill for the better Regulating the Affairs of the East India Company," upon which the Coalition Ministry was defeated in 1783. Fox had asked the painter to show the bill, and his finger pointing to it; and in Leslie and Taylor's "Life of Reynolds" there is a correspondence between Fox and the artist as to the representation of the document, in which Fox felt a just pride. Lady Hamilton as "Euphrosyne" (35) is a bright face, with smiling eyes, painted in vignette style by George Romney. T. Gainsborough's "Pink Boy" is a full-length standing figure of a boy in a red fancy costume, holding a red hat with feather. There is a graceful elegance in the figure, which is vigorously painted. The same artist's full-length portrait of Mrs. Lee Acton shows a pleasing-looking girl-like face, the figure dressed in white. Among other portraits are Sir Joshua Reynolds' "Kitty Reynolds" (48); William, second Duke of Leinster (44); Miss Pelham, daughter of Right Hon. H. Pelham, an excellent rendering of a pallid complexion in a black dress; W. Hogarth's portrait of Dr. Arnold, excellent in the colour and bluff countenance; and a few admirable portrait-pictures by Johann Zoffany, No. 27, "A Musical Party on the Thames," being particularly interesting as a group in which a family likeness is evident. Gainsborough's portrait of "Girl in a Straw Hat" is an admirable study of good features and a listless mood of countenance. A few excellent landscape and subject pieces meet us. We note especially Geo. Morland's "Cherry Seller" (6), transparently coloured; Henry Fuseli's "Nightmare" (15), a half-draped female with head dropping, and some hideous spectres above her; W. Van de Velde's charming picture entitled "A Calm" (18); a "Coast Scene," by Jan Van de Capelle; "Sunrise on the Coast," by William Collins (40), a pleasing bit of beach scenery, especially in the sea; David Teniers' "Brick-makers." That inimitable Dutch painter, Jan Steen, is represented by a few characteristic pieces, such as "Boors Quarrelling" (57), "Saying Grace" (54), "A Dutch Festival" (99), "Musician" (86). In these we observe that minuteness of detail, animation and spirit, and fresh colouring so peculiar

to his works. "Church of San Salute, Venice" (61), "View of Venice" (69), "Interior of St. Mark's, Venice" (238), "Giants' Staircase" (236), and some few more are charming views of architectural subjects, painted with that accuracy of detail and freshness and transparency of colour which so delight us in all Canaletto's works. The "Giants' Staircase," showing the courtyard of the Doge's palace, is a masterpiece of architectural detail and execution, while his views of the canal are too well known to need comment.

"Landscape and Birds," by Melchior de Hondcoeter (65), is a fine picture (the canvas being 61 x 79 in.) of a group in which a jackdaw, with a peacock's feather, is being vanquished by a game cock. The plumage is a masterpiece of imitative painting. The "Seven Acts of Mercy," by D. Teniers, is another painstaking work, executed with much detail, and chiefly clever is the grouping. The same great Flemish master is represented in several other pieces. We may name "Landscape, with the Château of the Painter" (75), "An Alehouse Interior," "Village Surgeon," as exhibiting the qualities of animation and grouping by which this realistic painter is best known. We are not sure, however, to which we must attribute these works—the elder or younger Teniers. "Ruth and Boaz" is a fine composition by Gerbrandt van den Eeckhout, in which Boaz is blessing Ruth, who is upon her knees. The yellow drapery and colour are admirable. We also note a "View in Amsterdam," by G. B. Heyse (painted 1685), a clever architectural piece; and an "Interior of a Church" (89), by Emmanuel de Witte. That master of still-life subjects, Francis Snyders, in a piece under that title (98) is represented in some finely-painted poultry, fish, and fruit—rather more to the taste of the gourmand in its coarse mixture. The lover of animal food will also find two magnificent pieces by the same master of fish of various kind, grouped in profusion on a bench (244, 227). Those who admire sea pieces will enjoy that of William Van de Velde (95) as a calm and pleasing example of that master; also No. 103. Tenderly painted is "L'Hôtellerie" (100). One of the finest subjects, upon a canvas over 7 ft. square, is entitled "Rinaldo and Armida" (126), from Tasso's "Jerusalem Delivered," canto XVI. Asleep under a tree, Rinaldo is about to be entangled in a wreath by Armida, attended by Cupids, and clad in flowing drapery. Painted by Sir Anthony Vandyck, this subject, exhibits all the powers of that great master of allegory and portraiture, and the grace of the figures and rich colouring are very fine and impressive. We must note, near, a sketch by Rubens for one of the paintings in Whitehall Chapel (130); the figures, brilliantly coloured and foreshortened, are seen from below. Other sketches by the same painter are classically conceived pieces from the Homeric story, in which Achilles is the chief figure. The panels are small, but are admirable as examples of decorative value (152, 153, 154, 159, 160, 161). These splendid sketches are lent by A. H. Smith Barry, Esq. Another grand conception is "The Assumption" (132), by Bartolomeo E. Murillo, a full-length figure of the Virgin floating in clouds and supported by angels. We have only space to allude to a great work, "Falls of Schaffhausen," by J. M. W. Turner (169); portraits of Sir Joshua Reynolds, J. Bacon, and Sir W. Chambers, by J. Zoffany (172), admirably painted; and to some most interesting paintings of the Early Florentine, Giotto, Da Vinci, Tuscan, Byzantine, and other schools, in Gallery IV. A very finely illuminated vellum of the "Descent of the Holy Spirit" and the "Decease and Glorification of the Virgin" (176, 177); a Virgin and Child, by S. Botticelli; a fine Diptych, by Taddeo Gaddi, of the 14th century; and that of the

"Virgin and Child, and St. John;" a fresco of St. Francis; a richly painted and grouped figure of "Virgin and Child;" (201); "Virgin Child and Saints," by Giovanni Bellini (203); also 205—must be particularised as examples of the earlier conventional paintings of sacred subjects. In some of these the expression and features are benignant and softly rendered; in others the countenances are by no means angelic.

Entering Gallery VII. we come to an interesting collection of cases of miniatures, lent by the Duke of Buccleuch, J. Whitehead, Esq., E. Joseph, Esq., the Queen, &c.; but we pass by them to notice a collection of drawings by the old masters, which for beauty and variety of composition and execution cannot be surpassed; and here the number of works prevent us giving more than a very inadequate notion of the most important and characteristic sketches. We select for notice more particularly the studies and sketches of Raphael, Leonardo da Vinci, Michael Angelo, Hans Holbein, Rubens, and Albert Dürer, in galleries Nos. VIII., IX., X. Those of Raphael have been largely contributed by the University of Oxford, the Duke of Devonshire, and the Queen. No. 109, a first sketch of Adam and Eve expelled from Paradise, is an exceedingly simple and expressive sketch in black chalk. The heads of Homer, Virgil, and Dante, in the fresco of Parnassus in the Vatican (113), is a mine of study in composition; it is in pen and ink. There is a grand instance of foreshortened limbs in "Group of Warriors," in black chalk (115), by Michael Angelo. Raphael's study of cartoon of "Elymas Struck Blind" (118), in pen and bistre, gives a faint idea of the artist's power for classical composition; but that master's group of "Figures Fighting" (124), and "Massacre of Innocents" (127), are, perhaps, unsurpassed for the life, animated expression, and spirited movement capable of being imparted to sketches. In grandeur of conception or grouping nothing can surpass No. 137—"Transfiguration," a study for the picture in the Vatican; "Virgin and Child" (141), a study for "La Madonna dell' Impannata," in the Pitti Gallery; study for the "Charge to Peter" (147). Most of these are drawn in red chalk or in pen and bistre, and are studies for frescoes, cartoons, and pictures, some of which are in the South Kensington Museum, others in the Vatican and Louvre. The studies include many that may be classed under the three styles followed by Raphael, verging from the religious feeling exhibited when under the influence of his master, Perugino, to the sublimer feeling under the Renaissance. When we pass to the studies of Da Vinci we cannot fail to notice the versatility of that great master of the Renaissance. The sketches have been lent chiefly by the Queen from a volume of the artist's drawings in Windsor Castle. We observe among them some remarkable studies of heads in pen and bistre, also machines, designs for castings, studies of horses' heads and limbs (169—180). The last of these shows a number of angular lines and proportions of the fore legs of a horse with notes in the painter's own hand. One of the most important contributions is No. 190, the "Holy Family," lent by the Society of Arts. It shows the Virgin, St. Anne, with the infant Jesus, and St. John, drawn to a considerable size in black chalk heightened with white. Vasari speaks of this very cartoon, executed at Florence, as a marvel which astonished "men and women, young and old, who came to see it when finished." The Virgin's face is extremely benignant and tender. We may remark also a series of studies of heads, shoulders, muscles of leg and foot, skulls, and other anatomical demonstrations, with notes in Da Vinci's own hand. Gallery No. IX. is filled with portraits by Holbein,

executed in the usual outline manner of that great artist. Many are drawn in black chalk or pen and ink on a tinted red paper, and have been contributed by the Queen. They represent heads, often in pairs, of the great men and ladies of his time. Thus, 224 is an outline of two heads, one inscribed "Tho. Wiatt, Knight," the other "S. Tho. Wiatt, K.; portrait of the favourite of Henry VIII., poet, savant, and statesman." Dated 1533. Full-length figures of Henry VII. and Henry VIII. (231) is a cartoon for a part of the destroyed fresco at Whitehall, painted in 1537. The entire composition is preserved at Hampton Court. This is a fine drawing in chalk, in which the figures and architectural accessories are effectively shown. So also is a half-length figure of "Jane Seymour, Queen," 245. We have little space left to speak of other masterpieces, but those of Michael Angelo cannot be passed over. Mentioning a few, we may point to No. 249—"A Study of Proportion of the Human Figure," in red chalk, with notes in the artist's own hand; 252, a study for the fresco of "Isaiah," in the Sistine Chapel, in bistre; a "Grisaille of the Cartoon of Pisa," in oil (255); a copy of portion of "Last Judgment," in Sistine Chapel (258)—a model of study worth close examination; "Three of the Labours of Hercules" (269), a spirited sketch of muscular movement; No. 302 equally striking as expressive of animation and movement of figures. In Gallery X. a few excellent studies by John Flaxman, R.A., are to be seen. "Visit the Sick" (359 and 365) are feelingly-conceived outlines, and exhibit many of the higher qualities of grouping and expression of that artist. We note other drawings by James Barry, R.A., Thomas Gainsborough, R.A., and several excellent studies by Claude and Rubens. The "Fall of the Damned" (436), in black and red chalk, is a grand conception of entangled human beings, with a fine warmth of tone; No. 440 is another vigorous sketch in water colours, heightened with white, but we cannot point to others of equal interest and value to the student of art. We consider the collection of chalk and bistre studies alone a school of immense value to the artist of figure and the decorative designer, and it is much to be wished that such an exhibition could be permanently maintained by Government or added to one of the national collections.

HOUSE DRAINAGE.

WE are glad to see at last that the doctors—although as yet only some few—are beginning to teach publicly that defects in house drainage are the cause of a great deal of the illness of the people of this country; and, inasmuch as a constructor is better than a repairer—a maker better than a mender—inasmuch, in short, as that prevention is better than cure—those medical men who have turned their attention to the means of preventing illness from poisonous air, food, and drink are likely to have a better time of it in the future than those who do no more than cure illness—great withal as is that act, undoubtedly.

Mr. Teale, an eminent surgeon of Leeds, has pointed out,* in fifty-five illustrations, the defects commonly met with in houses. Many of these have come under his own observation, others have been stated to him by medical friends, and others again by an architect and by a plumber, both of Leeds. The author considered—and we agree with him—that there was need of a book, the aim of which should be "to teach in as simple, telling, and unmistakable a way

as possible the faults of sanitary construction which it is within the power of landlord and tenant, as distinct from the public authorities, to remedy and avoid;" and accordingly his design has been to represent pictorially every important fault to which domestic sanitary arrangements are liable, or (in the words suggested to him by a medical friend) to produce "a clinical history of the defects to which drains are liable," and to point out the consequences of such defects by instances of the illness produced thereby. Mr. Teale does not profess to offer opinions how the various defects ought to be rectified, although he does, in a considerable number of instances, offer some good practical remarks thereon. To this apparent want of completeness he has two answers: firstly, that when we have discovered what is wrong we are more than half way to what is right; and, secondly, that in pointing out what is wrong he deals with unquestionable facts, while if he were to advise what ought to be done he would be in danger of going beyond his depth—of trenching upon the province of experts, officers of health, and sanitary engineers; and would be "touching on matters concerning which there may be various solutions, various opinions, and changes in course of time." This diffidence is to be regretted, as will be well understood by those who have, under the present state of circumstances, to devise proper sanitary constructions, or to remedy defects of those existing.

The subject is illustrated by fifty-five plates, with letterpress description of each. Although they are not drawn with any exactitude of scale or proportion, they very graphically show what is intended to be represented—as, for instance, the discharge-pipe from a lavatory, untrapped, and entering directly into a drain, or into the soil-pipe of a w.c.

Also, in the same way, the discharge pipe from a scullery sink, a kitchen sink, a housemaid's sink, a pantry sink, a dairy sink, a "save-all" tray in a water-closet, the dish-stone in the floor of a keeping cellar (or of any cellar or scullery), and the discharge pipe from a bath: also, in the same way, the overflow or waste pipe from a bath, lavatory basin, or water cistern. Plate 4 represents one of these discharge pipes from a kitchen sink entering directly into a drain without being trapped.

In one case stated (Pl. 10) the discharge-pipe of a lavatory basin is, indeed, trapped with the usual S bend; but this was rendered useless by the overflow pipe being connected with the discharge pipe below the trap, and therefore communicating directly with the house drain, and serving as a ready inlet of drain air into the house. This occurred in a house sold to a surgeon in Leeds as having been recently fitted up with all sanitary convenience and precaution.

Another instance of the effect of the escape of air from drains is described as follows (Pl. 28):—"In the dairy and larders of the new Leeds Infirmary there were found sink-stones practically untrapped in every instance. It is probable that this communication with the drains may have been the explanation of certain outbreaks of diarrhoea in the hospital, which were attributed to the milk, but without any such source of its contamination being suspected."

Where there are two or more water-closets, one over another, all discharging into the same vertical soil-pipe, the siphon bends being adjacent thereto, the water in the lower siphons is liable to displacement by the passage down the soil-pipe of water from an upper closet. The action takes place in this way:—When water is discharged from the upper closet, each siphon bend below it being filled with water and at

rest, performing its office of preventing the passage of air from the soil-pipe inwards, its rush down the pipe displaces a quantity of air equal to its own bulk, and rarefies the air immediately behind it; then, the air in the closet being under the full atmospheric pressure, drives the water before it out of the trap into the soil-pipe, and "unsiphons" the trap. This unsiphoning is more or less complete as the soil-pipe is smaller or larger in diameter. When it is small, the discharge of a gallon or two of water into it fills it, the water acting like a quickly-moving piston, and the air which follows it becomes highly rarefied, and in that case the emptying of the siphon bend is complete, by reason of the atmospheric pressure above mentioned; but if the soil-pipe be larger, so that the ordinary discharge of one or two gallons of water will not fill it, or nearly fill it, the air surrounding the water in its descent will be less rarefied, and the unsiphoning will be less complete, while with a sufficiently large pipe the action would not take place at all.

A soil-pipe should not be less than four inches diameter for one closet, or six inches for three, one above another; and in both cases should be carried up of the full size to, and above, the eaves of the roof; but not, of course, immediately below a window in a roof. Plate 14 is an attempt to show in a diagram the action of water and air above described.

Plate 7 shows how to correct the fault of the discharge pipe from a kitchen sink entering directly into a drain—first by trapping the pipe with an S bend; and secondly by making it discharge into (not above) a trap outside the house wall, having over it a grated opening, and the discharge pipe entering the trap above the water level.

In Plates 18 and 19 the defects of lead soil-pipes are shown. In a house recently occupied by a relative of the author, an old water-closet was removed, and the lead soil-pipe was found to be so rotten that "it crumbled like short-cake. It was open at the seam, so that not only gas, but liquid sewage had escaped." The eating away of lead pipes by sewage gases has been found mostly to have taken place in pipes which have been unventilated. The author points out the danger of leaving lavatories and water-closets long disused, because the water in the traps soon evaporates.

In Plate 22 is shown a common defect—or, rather, two defects, one of which is not remarked upon by the author. The one remarked upon is the termination of a ventilating pipe immediately below a window. The other defect shown in the drawing is the smallness of the ventilating pipe carried up from the upper bend of the soil-pipe.

By dint of persistent iteration, builders and plumbers have come to see that the soil-pipe of a water-closet must be ventilated; but as there never has been—and even is not yet—any command that the ventilating pipe shall allow sufficient room for the air in a soil-pipe to escape through it freely when a body of water is discharged into the soil-pipe, the plumbers have attached pipes (like this one in the drawing) altogether too small in diameter to allow the air to escape by that outlet—its passage through so small a pipe being much more difficult than through the basin into the closet, alongside of, and partly through, the water which passes out of the basin.

The ventilating pipe should in all cases be of the full size of the soil-pipe itself. There is yet in this drawing a third defect, which is that the end of the ventilating-pipe is turned downwards. It occurs in Plates 2 and 16, as well as in No. 22. Why turn the outlet downwards? There is no need to prevent rain falling into it—indeed, that is beneficial. Birds do not build their

* Dangers to Health: A Pictorial Guide to Sanitary Defects. By T. PRINGLE TEALE, M.A., Surgeon to the General Infirmary at Leeds. London: J. and J. Churchill. Leeds: Charles Goodall.

nests upon the open end, although that was once prognosticated. On the other hand, the abrupt bend offers great resistance to the passage of air out of the mouth of the pipe.

Plate 45 illustrates a case which is headed, "Poisoned by next-door neighbour's drains." The case was supplied to the author by Mr. Hewetson, surgeon, of Leeds, who having corrected every fault he could find in his house, it yet continued to be unhealthy, and did not lose the smell of drains until his next-door neighbour had his own drains inspected, when it was found that the soil-pipe passed beneath a set of stone steps common to the two houses, and that it had several openings in it. Another illustration shows the ravages which rats make when, through openings carelessly left in drains where one pipe joins another, they escape from the drain into the house. Other plates show, "How people drink sewage." Another, again, illustrates what a leading builder of Leeds stated to the author—that it was well known in the trade that speculating builders of cheap houses were in the habit of buying "seconds" drain-pipes at half-price (pipes which are broken, mis-shapen, and rejected).

On the use of road-scrappings and common house ashes, ground up with a bare pretence of lime, for mortar, and plaster for the walls of "miserable tenements," the author says: "In about sixty new speculators' houses not a single load of clean lime was used; mortar and plaster were made of lime which had been used in tan-pits, therefore spent and full of animal cleasings. The owners were the builders of the houses."

Plate 43 shows a case which touches a wide question. It has always been a difficulty with corporations and local boards—and latterly with all sanitary authorities—to secure proper superintendence of the laying of house drains. In this case a house was built at Halifax on "solid rock," in which the cellarage was excavated. This experience of its solidity seems to have suggested to the builder that it might be well, indeed, to lay the drain, as far as the cellarage extended, from one side of the house to the other; and also to lay, from the junction with the sewer (at a distance of about twelve yards off), one or two pipes (of course, as the author says, the authorities saw the junction made with the sewer), and in that state he left the work, with twelve yards of rock between the two portions of the drain which he had laid. It would appear, however, that this "solid rock" must have been a good deal fissured, for into the portion of the drain which lay under the cellar floor all the sewage of the house (including a w.c.) was discharged for seven years—that is to say, ever since it had been built—until, the children in the house being always ailing, the occupier took up the cellar floor, and found there a very large quantity of sewage, and found also the abrupt termination of the drain against the rock. Plate 47 shows a case which touches the same question. It is headed, "Economy in digging at the expense of fall in a drain." A sewer is laid at the proper depth to allow a sufficient fall for the house drains; but instead of giving the drain the proper fall, the builder gives it but little from the back of the house to within a few feet of the sewer, and then goes down precipitately to the junction.

In Plate 49 we are reminded of the necessity of a plan of the drains. Two or three men are searching for a drain under a house floor—"Hunting for drains;" but as there is no plan of the drains, there is no certainty where they will find any of them.

That houses should not be built upon the refuse from other houses, filled into old clay pits, and other hollows into which

rubbish may be shot, is pretty well known to our readers. This is what Mr. Teale says on the subject:—"Until recently no check has been put upon the haste of speculating builders, who have built thousands of houses on unhealthy rubbish-heaps, long before the animal and vegetable refuse has had time to ferment, decompose, and cease to be poisonous." These are the words of a medical man.

How to admit fresh air into houses is a question upon which the author offers remarks with some diffidence; but describes a method which he has adopted in a house of his own, the effect of which, he says, is that "the rooms are constantly fresh night and day, irregular draughts are much reduced, and, except in cold weather (an outside temperature approaching 32°) the ventilators are rarely closed." This is illustrated in Plate 53, and in No. 54 is shown another method of accomplishing the same object.

We recommend this book most highly. It shows, as the author says, work defective from ignorance and work defective from dishonesty. "Probably," he says—and it is quite true—"no work done throughout the kingdom is so badly done as work in houses, drains, and pipes, which is out of sight."

SCHOOLS OF ART.

DUNDEE.—At the eleventh annual festival of the Dundee School of Art the annual report which was read stated that the school had been successful in obtaining from the Government Science and Art Department, South Kensington, London, the following medals, certificates, and prizes, &c. :—In the second-grade examination, the subjects being practical geometry, lineal perspective, freehand, and model drawing, 112 students passed, and 46 obtained prizes; 2 students obtained third (highest) grade prizes for passing all the second-grade subjects in one year; 19 students obtained full certificates of the second grade, one of these being a drawing teacher's certificate of the second grade. In the third (highest) grade examination 8 students passed in third (highest) grade perspective; 4 of these obtained the mark good from the examiner; 2 students passed in third (highest) grade artistic anatomy; 17 students' works were considered satisfactory by the Department's examiners—10 of these in the advanced stages of art; 14 students obtained third (highest) grade prizes for drawing and painting from the east and nature, &c. In the science examinations the students of the school were very successful. In plane and solid geometry 1 student obtained a first-class certificate in honours, 3 second-class certificates in honours, 18 Queen's prizes, 6 second-class certificates. Thirteen prizes were obtained in machine construction and drawing, and 37 second-class certificates. In building construction 9 Queen's prizes and 26 second-class certificates were obtained. Three students gained national Queen's prizes, 1 a national bronze medal, 1 a national silver medal and 1 an art master's certificate. Two assistants had been successful in getting appointments as head-masters of schools of art during the year.

TAUNTON.—On Monday the prizes and certificates awarded to students were distributed by Sir Henry Cole, K.C.B. The treasurer's report complains of the continued falling off of receipts; the honorary subscriptions had diminished, and the school fees, which last year reached £180 in 1878, only amounted to £157. Mr. Rowe, the head-master, in his report stated that there were four more students than last year, and that the diminution in fees resulted from the increased proportion of evening students, and also from the irregularity of attendance of industrial students affecting the Government returns. For the 487 works sent up by 87 students for inspection 4 third-grade prizes of hooks were awarded. The local examinations in May were attended by 32 students, of whom 12 were successful, and 5 obtained full certificates as having passed in four second-grade subjects. Of outside candidates 33 presented themselves, and 3 were successful.

THE FEMALE SCHOOL OF ART.—The annual exhibition of the prize works of the students at the school is open in Queen's-square. The result of the past year shows that eight first-rank prizes were taken in the national competition by the Queen's-square students—the national gold medal, for a chalk drawing from the antique "Fighting Gladiator," by Mary Katherine Benson; the national silver medal, for a drawing from the same figure, by Ida Rose Lovering; a national bronze medal to Alice Hanslip for a drawing of the Laocoon, and another to Maud Ashley West. Four other national "Queen's prizes" were won by Ida R. Lovering, Ellen Ashwell, Edith Gibson, and Florence Reason. The gold medal given by the Queen was awarded to Anne Elizabeth Hopkinson for an oil painting of a group of fruit, with a silver cup and other objects. Important encouragement is afforded by the scholarships gained by the school. Of these, the Queen's Scholarship of £30 for one or two years has been taken by Elizabeth Mary Lovell; the National Gilchrist, of £50 per annum, for two years, by Charlotte Maud Havell and Harriett Ada Payne; while subscribers' scholarships of £20 and £10 are awarded to Catherine M. Wood and Florence Reason. The school has, besides the first rank places already mentioned, obtained no less than 38 of the third-grade prizes awarded. The Department of Science and Art have further signified their approval of the work of the school by purchasing the drawing of the "Gladiator," by Miss Benson, and the study from the life of two mice nibbling at cheese, by Miss Ashley West. The Queen also gave an additional mark of her interest in the success of the gold medallist, Miss Hopkinson, by purchasing two water-colour studies of flowers by her. The Royal Academy, after having examined the drawings from the antique by them, have admitted the following students to the schools:—Alice Hanslip, Ida Lovering, Mary Katherine Benson, Susan Ruth Canton, Frances Binns, Louisa Jacobs, Margaret Dicksee, and Alice Sarah Miller.

Plans are being prepared by Mr. Drew for the alteration and extension of the sewage farm of New Swindon for that local board of the town.

The Marquis of Northampton has presented to the museum of Northampton a collection of geological specimens, which has been classified and arranged by Messrs. Etheridge and Newion. The collection occupies twelve table cases, nine of which are filled with exclusively British, and the remaining three with foreign specimens, and it is regarded by geologists as scarcely equalled for completeness in the kingdom.

St. John's Church, Pembroke Dock, is being restored, and a heating apparatus added. The work is being carried out by Messrs. Jones and John, Government contractors.

Mr. Henry Roe, the rector of Christ Church Cathedral, Dublin, in reply to an address signed by over 120 persons of eminence, clerical and lay, asking him for an expression of opinion as to the removal of the screen in the chancel, to which a few Irish Churchmen object, has given as his answer that he differs in every respect from those who address him.

A costly brass lectern, valued at upwards of £100, has been presented to the parish church of St. Oswald, Oswestry. Messrs. Jones and Willis were the makers.

Earl Granville who presented the prizes to the successful students at the Hauley School of Art last week, referred to the distress existing in the country at the present time, and said he did not think any exceptional measures were required to relieve it. They must in the future look to the improvement of technical education, for without knowledge it would be as impossible for us to compete with others as it would be for a savage armed with bows and arrows to contend against a man who possessed arms of precision.

It is stated that a large plot of land in Myatt's-fields, between Camberwell and East Brixton—a district now being rapidly covered with houses—has been reserved for conversion into a public park and recreation ground, and that it will be forthwith laid out in an ornamental design.

An extensive fissure has occurred in the keep of the new military brigade depot, near Devizes, and precautions have been taken to prevent an accident resulting. The keep is over 120ft. high, and, together with the other buildings, was only completed about nine months since at a cost of £45,000. The tanks at the top have a capacity of 5,000 gallons, but have not yet been filled. The failure is attributed to frost.

TOMB OF EDWARD THE BLACK PRINCE AT CANTERBURY—
DETAILS OF PIANOFORTE—PUBLIC FOUNTAIN, CHIPPENHAM—
S. RAPHAEL'S HOUSE OF CHARITY, BRISTOL—
ALEXANDRA MANSIONS, VICTORIA-STREET—"BUILDING
NEWS" CLUB DESIGNS FOR VILLAGE CLUB HOUSE.

OUR LITHOGRAPHIC ILLUSTRATIONS.

PUBLIC FOUNTAIN AT CHIPPENHAM.

THE design which we illustrate is by Mr. W. Galsworthy Davie, architect, and was selected from among numerous others submitted in competition last year. It is now being erected, but the detail shown in the view is not being strictly adhered to. The bulk of the masonry is in red and grey granite, polished in parts, Portland stone being used for the carved caps and upper part of middle bowl, the panel of same being filled in with polished granite. The drinking trough for cattle is to be paved with glazed tiles, and the whole will rest on one solid bed of concrete. The work is being carried out by Messrs. J. Easton and Son, of Exeter.

SAINT RAPHAEL'S NEW HOUSE OF CHARITY, BRISTOL.

THIS building is now in course of erection from the design of Mr. Edward Henry Edwards, architect, of Bristol. It will be a large and substantial structure, harmonising well with St. Raphael's Church and Almshouses. The principal front, including the projecting bay of chapel, is 106ft. in length, and the north and south fronts measure 50ft. The basement comprises refectory and mission-room, with kitchens, &c. The ground floor—chapel, community room, visitors' room, parlour, hall (with groined vestibule), sacristy, dispensary, portress, and room of the "Mother Superior." The staircase will be of stone. On the first, second, and third floors are bedrooms and dormitories, with an infirmary (for the use of the inmates), with ante-room, &c. The walls are built of Pennant stone, with freestone dressings, the external chimney breasts and shafts being of brick. The cost of carrying out the design, exclusive of chapel fittings, will be £7,320. Mr. E. C. Howell, of Bristol, is the contractor, and Mr. Edward Honey the clerk of works.

PIANOFORTE.

AMONG the specimens of English furniture shown at the Paris Exhibition, Messrs. Henry Ogden and Son, of Deansgate, Manchester, exhibited an inlaid satinwood pianoforte. The instrument, which we illustrate, is designed and worked out in the Adams style, the decorations being all inlaid woods beautifully shaded, and afterwards further relieved by the graving tool. The ordinary heavy look of a grand piano case has been avoided by introducing panels all round the sides and end, divided by framing and pilasters in mahogany. The more important panels are inlaid with appropriate figure subjects and trophies of musical instruments. The legs are square-tapered, with sunk inlaid panels on the sides, having carved and gilded capitals, and terminating with castors. The reduction necessary for our photo-lithograph renders the description of the details on the plate itself partially inaccurate. They are really shown about one-fifth, not one-third their real size.

A VILLAGE CLUB-HOUSE.

THIS design, by "S." in circle, is the one we awarded second in our Designing Club Competition, the first place being given to the design by "Triangle" in a circle, whose plans we published in the BUILDING NEWS for Dec. 27 last. The two designs ran each other very close, and we had some difficulty in determining which was the better of the two, but our detailed notes on these and the other designs of the same series will be found in our issue for Nov. 29 last.

TOMB OF EDWARD THE BLACK PRINCE, CANTERBURY.

EDWARD the Black Prince's Tomb, of which we give an illustration, is situated in Trinity Chapel, Canterbury Cathedral. This tomb was erected according to the prince's will, and is the most authentic memorial of the first of a long line of English heroes, and a fine specimen of the architecture of the period. The prince died on Trinity Sunday, June 8th, 1376; he had previously founded a chantry in the crypt, on the occasion of his marriage with the Fair Maid of Kent, 1363, in which he desired in his will to be buried; but for some reason this was not done. The effigy is in brass, and was once entirely gilt, and shows distinctly the Plantagenet features—viz., the flat cheeks and well-chiselled nose, resembling those of his father and grandfather at Westminster Abbey and Gloucester. Above are suspended his brass gauntlets, "the heaume du leopard," his casque, lined with leather, his shield of wood, covered with moulded leather, his velvet surcoat, with the arms of France and England, and the scabbard of his sword. The sword is said to have been taken away by Cromwell. Round the tomb are escutcheons of arms, charged alternately with the bearings of France and England quartered, the shield by which the prince had distinguished himself in the battle-field, with the ostrich feathers, and the motto, "Houmont Ich diene." Above is an inscription, said to have been composed by the prince himself:—

Tu q' passez ove touche close, par la ou cest corps repose
Entent ce q' te diray, sicome te dire la say.
Tiel come te es, je autiel fu, tu seras tiel come je su.
De la mort ne sensay je mie, tant come j' avoy la vie.
En terre avoy grand richesse, dont je y fya grand noblesse.
Terre, mecons, et grand tresor, draps, chivalx, argent, et or
Mes ore su je povres et cheitifs, perfond en la terre gys.
Ma grand beaute est tont alee, ma char est tonte gastee.
Mont est estroite ma meson, en moy na si verite non
Et si ore me veissez, je na guide pas q' vous decidez
Qu' j' eusse onges pour este, si su je ore de tont changee.
Par dieu pries au celestien Roy, q' mercy ait de l'arme de moy.
Tentel q' par moi prier ont, on a Dien m'acorderont,
Dieu les mette en son paraye, on nul ne poet estre cheitifs.

There is a representation painted on the canopy of the Holy Trinity, which he revered with peculiar devotion; there are also hooks for the hangings bequeathed in his will, black with red borders, with "cygnes avec têtes de dames."—F. W. RICHARDSON.

ALEXANDRA MANSIONS, VICTORIA STREET.

THIS building, when finished, is intended for residential purposes, each floor containing four residences or flats. The accommodation in each is varied, and in addition to the stone staircases shown on the plans, lifts—tenants' and servants' ditto—will be provided for the service of all floors. The design partakes somewhat of the French Domestic Gothic style, the whole of the exterior being of stone from the quarries of Mr. John Alford, of Tisbury, Wilts, all well worked and fixed by Mr. W. Slack, of Croydon; Mr. D. T. Haylock was the clerk of works. The buildings generally are similar in intention and design to the "Members' Buildings," situate in Victoria-street, and designed by the same architect, Mr. Francis Butler. Illustrations of this latter erection, and descriptions in greater detail will shortly appear in the BUILDING NEWS.

COMPETITIONS.

LAMBETH INDUSTRIAL PAUPER SCHOOLS.—At a meeting of the guardians of Lambeth Union, held on Wednesday week, a report was received from Mr. Currie, to whom had been referred the plans sent in in competition for the reconstruction of the pauper schools at Lower Norwood. He recommended that they be placed in the following order of merit:—"Light and Air," estimated cost, £20,070; "Terra Cotta," ditto, £33,700; "A Katepayer," ditto, £25,101 18s. 9d. On opening the sealed envelopes it was found that the first premium (£150) would, if Mr. Currie's recommendation were adopted, fall to Messrs. Coe and Robinson, 4, Fumival's-inn; the second (£100) to Messrs. F. H. Fowler and Aldwinckle; and the third (£50) to Mr. Edward Clarke, 6, Adam-street, Adelphi. The further consideration of the plans was referred to a special committee.

MARSHES-ROAD BOARD SCHOOLS, NEWPORT.—A letter has been forwarded to the School Board for Newport, Monmouthshire, and also to the local press, by Mr. Geo. H. Davies, one of the competitors for the schools in Maraes-road (the tenders for erecting which appeared in our last issue). He states that designs for these schools were invited and received from architects of Newport before January 18, 1878, and adds:—"The plans having been sent in in due course I was some time after greatly surprised to learn that a gentleman, having had the advantage of studying their details, was allowed to introduce an entirely fresh design, and that this, after various modifications, was to be finally accepted, although complying in no essential respect with the board's previous instructions. That there was in this a clear moral and legal breach of faith cannot be seriously denied. The absence of the courtesy usually extended to architects in similar competitions has also been remarkable—the receipt of the plans was not in any way acknowledged, the architects have not been informed of the result, thanked for their time and money uselessly expended, their plans not sent back, nor have they been told to fetch them away. On removing my own I find them seriously injured by dirt, &c." Mr. Davies says that the matter is now, so far as he is concerned, a closed and unfortunate transaction, and that as time has moderated his feelings he does not intend to renew ill-will by taking legal proceedings.

Invitations have been sent out from the architect's department of the Corporation of London to firms eminent in the art of designing public gardens to send in designs for the embellishment of the grounds to be formed out of the churchyard of St. Paul's Cathedral. The work, which is to be extended to three sides of the cathedral, will probably include improvements of an extensive nature, as well as some alterations to the outer railings. The scheme in its full details has not, however, according to the City Press yet been finally decided upon.

The thirty-first annual ball in aid of the Builders' Benevolent Institution will take place at Willis's Rooms, on Thursday, January 30.

The clock, bells, and carillon machine, supplied for the new Manchester Town Hall by Messrs. Gillett and Bland, of Croydon, were started last week.

A new tragedy about to be published by Messrs. Longmans and Co., entitled "Brian Boru," by "J. T. B.," is the production of a member of the architectural profession.

A new school-chapel, vestries, keeper's-house, &c., are about to be erected for the Wesleyan body in Plymouth-grove, Manchester, from the designs of Messrs. Hetherington and Oliver, of Carlisle. The site is a capital one, and in this preparation of the plans, provision is made for the erection of a large chapel at some future time, to seat 1,000 persons, with a lofty spire 140ft. high. The buildings will be in the Early Gothic style.

The tunnel sewer in course of formation at Boscombe Chine for the discharge into the sea of the sewage of Bournemouth, was burst open, and partially destroyed on Wednesday week, by an influx of storm-water. The mishap, which will cause considerable pecuniary loss, is attributed to the fact that the sewer was begun, in accordance with instructions from the improvement committee, from the inland end in connection with two other large sewers, and the surface-water collected by these, poured into the tunnel to which no proper outlet had as yet been formed.

The Spanish Cortes have voted 100,000 pesetas for the reparation of Cordova Cathedral.

THE NAVE ROOF, ST. ALBAN'S.

A VERY few words will suffice to close this correspondence as far as I am concerned. Any one who will take the trouble to look again at my letter will see that Mr. Scott has omitted to answer it on most points, whilst those on which he does write do not affect the main issue.

He refers at length to his reports. Of these, save one of June 25th, I know nothing. That was complete in itself, and I agreed with it, and have spent some time in supporting its recommendations—hoping when I began that I was helping Mr. Scott's object. It is true that it began by referring to the western part of the roof, but as it finished by speaking of what would then have to be done to the whole of the ceiling, I concluded that the eastern part of the roof had already been dealt with in some report which I had not seen. I will only add that—if language means anything—making an old roof “sound and serviceable” by repairs does not mean erecting a new roof over and independent of it.

If Mr. Scott will read what I have written more carefully, he will see that I have always asserted that the walls of the nave and transepts originally finished at the same level, as consequently did their roofs. The nave walls, being now higher than the transept walls, must evidently have been raised. I have stated this clearly from the first, and cannot understand why Mr. Scott assumes that there is any possibility of my being in doubt about it.

As to the new parapets to the western part of the nave I thought I had made myself clear. The *corbel-table* under the parapet is, I doubt not, a copy of the old corbel table, but the *parapet* above it did not appear to me to be copied from anything of the same age now existing on the church.

I am very glad Mr. Scott is going to have the south transept gable accurately measured. With this, and the old doorways in the tower and the marks of framing on the old timbers in the nave roof, he will be able—as I pointed out to the Society of Antiquaries—to reconstruct on paper, with a close approach to accuracy, the positions and pitch of the Norman roof and the design of the latest high-pitched roof of the nave, to which no doubt the old timbers belonged. These would be very interesting particulars, and I regret that they were not obtained before any illustration of the supposed lines of roof were published. But without this information Mr. Scott's illustration affords—to say the least—very strong evidence against the line, which he calls that of the original roof, being in fact anything of the sort, even if it exists anywhere save in his own imagination.

GEORGE EDMUND STREET.

Everything that can be done ought to be done to discover, and to bring before the public the facts relating to the existing remains, and the evidences of the architectural history of the several roofs which have covered the Abbey Church of St. Alban's.

A fresh interpretation of the facts recently brought out as to one very important detail may serve to throw light upon the proper solution of the present controversy—at all events, as to the true state of the case, whether the eventual result may be affected by it or not. Until recently little has been accurately known, except perhaps to those personally interested in the work, respecting the relation of the existing parapets to the present or to previous roofs, or as to what was really proposed to be done in their restoration or renovation, as the case might be.

Mr. Street's reply to Mr. J. O. Scott's report will have made clear to those who have at all looked into the matter for themselves, what Mr. Scott's report, in the absence of his diagrams, failed to do.

And I must express my amazement at finding it not only supposed but seriously and de-

liberately maintained—1. That the original Norman roof extended so far above the principal string-course of the tower as to cut through the jambs of the windows over. 2. That the lines of the roof-chases in the tower wall, now filled in, but still so conspicuous and so clearly indicative of the original Norman roof, are not the lines of a Norman roof at all, but of a later mediæval roof cut down from the steeper pitch. 3. That this lower roof ever coexisted with the parapets, or would be in any way at all compatible with them. 4. That the present proposal to construct a new steep roof to the lines of this lower roof would preserve in any way or in any sense be a “restoration” of whatever had existed or ever could have existed at any one period.

I do not now propose to enter into the merits of the question as to what ought to be or is to be done by the restoration committee. I can freely admit, as I took the opportunity of doing at the meeting of the Society of Antiquaries, that the high ridge line, if kept within the limits of the apex of the walled-up chases of the original work, would be better æsthetically, and would produce much more nearly than it does at present the effect intended by the original builders, and the appearance which the abbey presented in its palmiest days. But I must confess I do not see how it is to be done in any way which shall be compatible with the principles of “faithful restoration,” and I do most emphatically protest against its being urged or attempted upon any one of the grounds set forth in the four propositions enumerated. Let it be done as “the best thing” or as a “vast improvement,” as a necessary expedient, as a legitimate development of 19th century work, as a concession to weakness, or as an irresistible act of irresponsible power, only let it not be promoted and defended upon grounds which shall utterly stultify the boasted enlightenment of the present generation in the study and preservation of mediæval architecture.

I speak strongly, but surely not more strongly than the rights and the urgency of the case demand, and I will be no party to this question being made a personal matter; but when eminent amateurs charge the whole architectural profession with ignorance and with wanton destructiveness it would be doing a lasting injury to the interests which we have at heart to let pass such flagrant vandalism as that of the triumph of might over right in these days of free enlightenment and investigation. And this is the more needful at the present time, and in the present instance, when an energetic body of men, self-constituted for the very purpose of the “conservation of ancient remains,” has left the battle of conservation to be fought out single-handed by those whom it has thought well to denounce in no measured terms for their wanton destructiveness. There has been “much cry and little wool.” They seem to have taken no steps—at all events, no effectual steps—either for investigating the facts or of appealing to the popular enthusiasm for the conservation of the ancient remains. Discretion has proved, in this case at least, the better part of valour. It would have been a thankless and up-hill task for them to have undertaken; and the preliminary investigation is one from which they might well shrink. Much has been said in the public papers, but no sufficient information which could be relied on had been given as to the structural question now raised when it was announced that the steep roof was already decided on. And in August last I wrote to the *Times* suggesting that there ought to be a conference of architects to investigate and report upon such existing evidence and indications as could be discovered, and had not, up to this time, been communicated to the papers, in order that the public might be in some position to appreciate what was going on. Being the dull time of the year the *Times* seemed to think such a suggestion superfluous. Happily, the same idea occurred to other minds, and through the instrumentality of the conservation committee of the Institute the conference was held of which we now have the result.

My own visit to St. Alban's was an entirely voluntary and independent one, and the section, which I made showing the line of the Norman roof to have been at an angle of about

45° with the horizon, and to have run down on to the corbel-table, from which the parapet springs, agreed with the section exhibited by Mr. Street. The remains which are actually found to exist accord accurately with what naturally would be expected by the circumstances of the building, and by comparison with others of a similar character. The angle of slope, the position of ridge, the relation to the corbel-table, the indication of the line of rafter on the original walls, the relation of the rafter-line to the corbel-table, all go unmistakably to corroborate each other as to its original date and treatment. It is true that doubt has been thrown upon the date of the corbel-table, but I think an examination of its construction and of its section, of which Mr. Neale has kindly favoured me with a full-sized profile, convincingly shows it to be the original one. It is equally clear that the string-course immediately over it, and forming, as it were, a part of it, was an addition of the 14th century, when the parapets were built—when also it is probable the angle bridges against the tower were added. This, however, is not of so much account.

Now, the alleged traces of the steeper roof upon the tower walls, which have been so effectually obliterated as to be scarcely visible, are almost ignored by Mr. Street, and according to the clerk of works always were very dubious. It seems, however, according to Mr. Scott, that they really existed, and indeed were regarded by him as indicating the line of the Norman roof. No other attempt seems to have been made either to explain them or to explain them away, excepting that Mr. Street very properly denies that such a roof could have been the Norman one, unless it were *lifted* when the walls were raised. Neither of these suppositions will be found to be satisfactory as an explanation of the facts.

There is, however, as yet nothing to show the exact or even the supposed line or angle of this high roof, and until Mr. Scott shall have produced this it may be difficult to explain it satisfactorily. But apart from the evidence of its existence being established it is not only possible, but probable that such a roof with parapets may have been put up in the 14th century above the old line of the Norman roof, and cut down again in the 15th or 16th century, not to the intermediate pitch of about 45°, but to the present flat one, 18°.

This supposition will account for the existence of the string over the corbel-table being of the 14th century, at which time the parapet would be first built, and also for a subsequent raising, perhaps in the 15th or 16th century, of the wall, and probably of the parapet also, when the roof was cut down.

A very customary and probable slope for such a roof within a parapet would be an angle of 60°. Neither the carrying up of such a roof, cutting, as it is said to have done, into the windows above the string, nor the cutting it down again below the ridge of the original one, would be at all at variance with the practice of the men of the respective periods. It is what we find again and again has been done, and it will reconcile with each other the conflicting difficulties raised.

All this, however, will not go to remove the difficulty, but rather to increase it, if the old roof be doomed to destruction. It would be preposterous to raise the ridge of a new roof beam to cut into the window over the principal string, and it would be impossible to follow the line of the old Norman roof with the existing parapet. The only mode of dealing with it would be indefensible, except by way of radical innovation. The striking out of a new line of rafters from the present gutter to the line of the old Norman ridge would be an expedient, possibly a deplorable one; but by no treatment short of destroying all the present parapets could there well be a restoration to what it was at any period. Possibly the committee may resolve still that radical innovation will be the best way out of the difficulty, only let it not be called “faithful restoration.”

This course will at all events disarm the power of future adverse criticism by destroying the only vestiges by which it could be made effectual. Of the condition of the roof I am not prepared to speak. I have been told that it is in such a state that, though an estimate

has been given for its repair, the builder would not undertake it as a contract. On the other hand, it has been reported well capable of repair. And if it be so there seems no reason for replacing it with one upon new lines, and essentially of modern construction.

WILLIAM WHITE, F.S.A.

My communication in your last week's issue contained a few inaccuracies which crept in owing to its having been written in a hurry, and corrected by means of post cards. Speaking of an expression I had used previously, which was liable to be misunderstood, I am made to say that it had no "reference to himself." This should have been "myself." At the end of my letter, it is stated that certain work "was all done before I came on the scene." This should be read, "was all arranged for." The other inaccuracies are only verbal.

J. OLDRID SCOTT.

THE LEGAL RESPONSIBILITIES OF ARCHITECTS.—II.

(Continued from p. 703, Vol. XXXV.)

AN illustration of the American practice is found in the case of Newman v. Fowler, decided in New Jersey in 1874.

A house after completion proves defective; the report of the case does not say in what respect, but it is found that there was want of care and skill on the part both of the architect and of the contractor. On the principle that when several persons are concerned in inflicting injury upon a man, any one of them is liable for the whole damage, and that the person wronged may choose which he will compel to pay the indemnity, the owner sued the architect for the entire damage. The jury was charged that where the negligence of the contractor was such as to be discoverable by the exercise of reasonable care and skill on the part of the architect, the architect and the builder were alike responsible; for the effects of negligence of the builder beyond this measure, he alone was responsible. In this case the negligence or unskillfulness of the architect being admitted, his sameness of accountability with the builder was a necessary consequence, and the owner had a right, if he chose, to obtain from him the full damages, and judgment was given accordingly.

A point in this case is interesting. The owner had kept back a part of the contract price from the builder, on account of defects not specially described. The defendant's counsel claimed that by so doing he had already obtained indemnity from the builder, and could not demand further damages from the architect. The judge's reply was that if the builder had sued the owner for the balance of the contract money, and the defence had been that it was retained on account of the same defects for which the present action was brought, and the defence had prevailed, it would have barred the present action against the architect, since the owner was not entitled to obtain damages twice over—once from the contractor and again from the architect. But in fact the builder has not sued for his money, and there was no evidence that the owner might not have retained it on account of other defects than those for which he was suing the architect, so that the question of the retained balance was still open and undecided, and could not be considered in the present action.

Another case, decided in Missouri in 1876, gives an idea of the care which the law considers to be required of architects. A building was in process of construction, and iron columns and girders had been set to carry some portion of it. By defect, probably of the foundation, two of the columns settled after the weight was brought upon them. The architect proposed to raise them with the girders resting upon them, apparently so that they might be underpinned. It was in evidence that one of the contractors who furnished the ironwork, hearing the architect propose to apply jack-screws under the caps of the columns, advised him not to do so, as he did not think the existing strong enough; but the owners took the architect's view, and on his recommendation employed a professional building mover for the work. It appeared that there

was some stipulation that this man should work under the direction of the architect; if it had not been for that, the judge's opinion was that the architect would not have been liable for the improper management of the raising which was alleged by some of the witnesses. On the application of the jack-screws the cap of one column broke at the corner, and the flange of the compound wrought iron girder resting on it bent, allowing the girder to fall, bringing down a wall with it, and killing a workman employed in the building, whose widow sued the architect for compensation for her loss. The architect himself was not in the building at the time, but knew and approved of the method adopted to effect the raising. The judge charged the jury that if they found that the disaster was due to an improper method employed for effecting the raising, or because of inadequate supports for the screws or unskillful application of them to the columns, while the work was under control of the architect, he must be held to have shown negligence in business which he undertook, though he failed to show the care and skill which, having undertaken it, the law imposed upon him, and was liable for the damage resulting from his negligence. Some of the testimony went to show that the design of the girder was bad, and that the columns were weak and badly cast, and the jury were charged also that if they found that defective ironwork was the origin of the accident, and that this was designed by the architect in an unskillful manner, or was defective by means of bad material or workmanship, which could have been discovered by the defendant, in this case also he was guilty of a negligence which rendered him liable for injury resulting from it. The judge thought that the absence of the architect at a time when so critical an operation was going on was in itself a failure to show the care required of him, and thought also that he was guilty of neglect in not having the strength of the caps of the columns tested before subjecting them to so severe a strain; and the jury taking a similar view, the defendant was obliged to pay the amount claimed, 5,000 dollars. The court, in this case, was of opinion that the owners of the building were liable, together with the architect, but it is not very evident why; and in an English case of manslaughter from the falling of a building, the owner, who proved that he had given orders for good and substantial work, but knew nothing of construction himself, and had not controlled the details of the execution, was discharged.

The professional man must not forget that the damage for which he may render himself liable by remissness in duty extends beyond loss by deficiencies in the construction. A distinguished architect in London was accused of negligence in failing to prepare plans for a certain alteration with due rapidity, and the proprietor, who let the rooms in the building to lodgers, claimed the profits which he would have derived from his house if the work had been finished without delay, and the court decided that he was entitled to recover them. It would seem, therefore, that there is no want of law to hold the architect to his duty to his employer; but if the courts set up a high standard of professional diligence and skill, it must be acknowledged that their requirements are on the whole reasonable and just to all the parties, and the practitioner, conscious of having done his work with faithfulness and skill, can appeal with confidence to a jury against the oppression of an ignorant or avicious client. Every step that is made toward a clearer definition of our duties helps us to a recognition of our rights, and if the public should learn to hold us generally to a stricter accountability and a higher standard of skill, those who desire the advancement of the profession will rejoice, not only in the necessity for higher attainment, but in the increased respect and easier relations with the world which recognised acquirement and responsibility will give.

But there are certain branches of an architect's duties towards others than his clients, which are by no means so well defined. An important case decided in the House of Lords after long and costly litigation raises a very interesting point. A contractor named Thorn

was invited to estimate on plans and specifications for rebuilding the Blackfriars Bridge. His bid was accepted, and a contract, of which the specification formed a part, was signed. The engineer had designed to construct the bridge piers by means of iron caissons, sunk in the river and filled with masonry, and the plans and specifications were drawn to that effect. In execution the caissons proved too weak to sustain the water pressure, with the force of the current, and the upper part had to be removed, and the work finished by the slow and costly process of building only when low tides permitted. When the bridge was finished the contractor sued the Mayor and Corporation for damages for the insufficiency of the plans and specifications, alleging that by offering them for estimates the Corporation virtually guaranteed that the bridge could be built in accordance with them. The Corporation replied that there was no guaranty, express or implied; that while they placed confidence in their engineer, Mr. James Cubitt, they did not pretend to warrant his work; that the contractors knew as much of him as the Corporation did, and if they had wished, they could have had an engineer of their own examine the plans and pronounce as to their practicability, and if they had then wished to withdraw their proposal they might have done so; and the unanimous opinion of the judges was that this defence was a good one, and judgment was rendered for the Corporation.

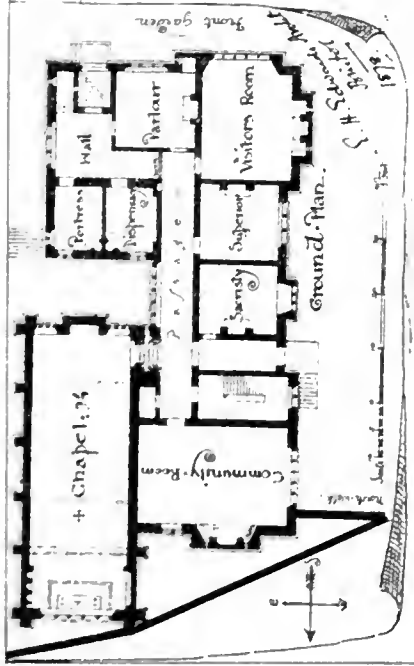

According to the Lord Chancellor, the same principle should apply in every case where a man employed an architect to prepare plans and specifications, and invited estimates upon them.

It being thus settled that the first party to a contract does not guarantee the plans and specifications which form a part of the contract, it is of the highest importance to determine whether the expert who drew them could be understood to have guaranteed them. In the case of the bridge the engineer was dead before the action was brought, unfortunately for his professional brethren, who could have derived much instruction from seeing the result of a suit brought against him; and there appear to be few or no recorded cases of the kind, unless in French practice.

Another subject which gives trouble to a conscientious architect is the proper adjustment of his duties between the builder and the owner. In case of dispute between the parties to the contract, he is made the judge by universal custom, and even in court the architect's position as umpire between owner and contractor is so well recognised; that his testimony is generally the most important part of the evidence; yet how does such a position agree with the rule of law that a man can act only in behalf of one person at a time? The owner engages him, and bears alone the cost of his employment; is he not then solely the agent of his employer? And if so, how can he act as umpire between his principal and the opposing party?

That this is a serious question every one in practice has occasion to know. Cases happen every day in which a contract open for estimates is awarded at a price which the architect, who has the other bids as well as his own judgment to guide him, knows to be less than the value of the work; is it his duty as agent of his employer to accept the proposal which he sees to have been based on some misunderstanding or error, and set himself to drawing up a contract so framed as to protect his principal from loss in case of the bankruptcy of the builder which he knows to be inevitable? Or has he a right to constrain his principal to accept a bid at a fair price, or to call the attention of the incautious bidder to the probability of an error in his estimate? If he takes advantage of the ignorance or carelessness of the builder, to the benefit of his employer, has not the builder a ground of action against him? And if in pity for an honest mechanic who has made a mistake in adding up a column of figures, or who, not being very expert in reading manuscript, has been unable to spell out all the words in the specification, he has given him a hint of his misunderstanding, has not the owner, who is thereby obliged to pay a larger sum than with skilful management he otherwise would have needed to spend, a right

to accuse him of unfaithfulness to his trust, and to claim damage from him?

Such questions have a serious bearing not only on the professional conduct, but on the peace of mind of a conscientious practitioner, and any discussion or citation of cases which have been decided that may tend to a general understanding and uniform practice in similar matters is one of the many things of which the profession is in great need.

HEATING HOUSES BY STEAM.

THE system of heating houses by steam, inaugurated in a very modest way at Lockport, New York, not without serious misgivings, has, according to the *English Mechanic*, hitherto worked so well that an experiment is to be tried in New York itself. The Holly system, as it is called, consists simply in laying on steam to houses in much the same manner as gas or water is laid on, the steam being generated at the "works," and conveyed through pipes, properly clothed with some non-conducting material, to the places where it is to be used. The first experiment was made at Lockport, near Niagara Falls—a town situated a little north of the 43rd parallel of N. latitude. In June, 1877, the experiments were commenced by laying half a mile of pipes underground to obtain a datum for calculating the carrying capacity of tubes, and the rate of loss by condensation. The results were encouraging, and before the winter set in about three miles of piping, mostly 4in., had been laid down, the greatest continuous length being one mile and a third. Although Lockport is some 8° nearer the equator than London it is considered to be a cold region, and the test made by the company in the winter of 1877 was, therefore, regarded as practically demonstrating the feasibility of the scheme. Since the commencement of their operations the company has efficiently warmed about forty houses, a large school-room, the town hall, and, besides supplying steam for other purposes, have run two steam-engines, one of them situated about half-a-mile from the boilers. Some of the houses were more than a mile from the source of heat, but were warmed as satisfactorily as those near the boilers.

Steam heating will enter a new phase of its history in the spring, for in spite of much opposition the promoters of the Holly system have convinced the Mayor of New York of the advantages of their scheme, and he has recommended the Board of Aldermen to give the Commissioners of the Sinking Fund power to grant privileges to certain persons to carry steam for heating purposes underground in New York city, and as this recommendation is tantamount to a grant of the privilege, it is supposed that some portion of the city—perhaps a quarter of a mile or so square—will be granted the Holly combination. The proposals of the companies cover a wide field, but as it is essential to the success of the plan to utilise the steam to the utmost, it is probable they are not overstrained. It is proposed, first, to heat houses, offices, depots, &c.; to cook by steam in one of several patented stoves already invented; to heat water, to put out fires, and to clear the streets of snow. Figures are of course brought to bear on the question, and we give them here for what they are worth. To warm the public buildings of New York costs now £120,000 a year, whereas with steam it could be done as efficiently at an outlay of £30,000. For removal of "ashes" a sum of £45,000 is annually paid in New York, but ashes include rubbish and snow, so that it is only the ashes proper that can be taken into account, and their removal costs in reality nothing at all; still, there is an avoidance of the nuisance of ashes which every housewife will appreciate. Five shillings a load is now paid for the removal of snow, but with a system of steam hydrants and hose it is stated that a "load" can be melted in 20 minutes at about one-tenth of the present cost. By dispensing with fires in houses it is estimated that insurance rates would be reduced by at least 1 per cent., while there would be no expenditure of labour in cutting wood, carrying coal, and attending furnaces. The arrangements inside the house are of so simple a character that a child might

regulate the whole apparatus, while the company can control the pressure so as to supply any house with steam of 200lb., 20lb., or 2lb. if needed. Exactly how that is done we are not informed, and in the absence of details we may venture to doubt the accuracy of the statement, as we do the assertion that the companies can supply steam-users with power at one-half the cost from their own boilers. The experiment to be made in New York will be watched with much interest, and though there is small likelihood of the plan being tried here on a large scale, there is no reason why some of our large establishments should not make the experiment, and make it successfully.

SKETCH OF OLD LONDON.

WE lately noticed a very interesting collection of views and maps of Old London arranged for exhibition at South Kensington by Mr. Crace, senior, and we have now on our table "A Sketch of Old London its Streets and Thoroughfares before the Great Fire of 1666," by Mr. J. G. Crace, his son, being a reprint of an address on the subject delivered by the author at the Society of Arts at the request of the Council. Of course we lose some of the interest in the absence of the splendid collection of prints by which the address was illustrated, and we hope Mr. Crace will, on some future occasion, amplify his lecture into a volume, in which case a few of the maps and views would be a pleasing introduction. The foundation of the City of London is very obscure, and Mr. Crace does not throw any new light upon it, though he says it is certain that the city existed before the Roman occupation of Britain. A remarkable fact recorded by Mr. Crace is, that no mention of London occurs in the Domesday Book, though in King Henry II.'s reign Fitz Stephen, a monk, wrote "A Description of the Most Noble City of London." The author quotes at some length from this document, which will be read with interest. The early chronicler speaks highly of its wealth, great trade, and grandeur, of the politeness of its citizens, the three principal churches, and says "the matrons of the City are perfect Sabinas." Up to this time (the 12th century) written descriptions only exist, but Mr. Crace's narrative properly begins at the 16th century, for it was not till that time any reliable plans or views of London existed. The author then draws a graphic picture from the fine maps and views collected by his father, and which we have already glanced at. He begins by referring to a very interesting view, copied from a Dutch drawing by an artist named Van den Wayngerde, now in the Bodleian Library, forming one of a series supposed to have been drawn for Philip II. of Spain, about 1540. We have referred to this map in our previous notice. The map of Ralph Aggas, the earliest plan known to exist, engraved in 1563, is then mentioned, after which the view by Visscher, published in 1615, a fine view by Hollar, engraved in 1649, a map by Newcombe, 1645, &c., are given. Mr. Crace, in his pleasant imaginary journey from Oxford to the City by way of Oxford-street, then called the "Way to Tyburn," gives us some interesting facts. The village of St. Giles, with its hospital and church, the road called Holborne (after the "Old Bourne"), Chancery-lane, Ely House, St. Sepulchre, Smithfield or the "smooth field" as it was called, are commented upon. Passing in review other memorable parts, he reminds us that Somerset House was designed by John of Padua, for the Protector Somerset, and was built on the site of the Bishop of Worcester's and other houses; that Durham House was the residence of the bishops of that see, and afterwards of Dudley Earl of Northumberland; that Sir Walter Raleigh resided there, and subsequently that it fell into the hands of Robert Earl of Salisbury, who demolished the stables next the Strand, built an exchange called Britain's Bourse, after which, in 1770, the Brothers Adam built the Adelphi-terrace. Westminster is next described, also Old St. Paul's; and the picture is finished by a reference to changes in the latter half of the 17th century, and by a quotation from Evelyn's Diary of his account of the great fire, which began on the night of September 2nd, and which, in a few days, completely destroyed Old

London. We commend Mr. Crace's pamphlet as a guide to those who visit the large exhibition of engravings at Kensington.

HOUSE FITTINGS FOR WATER SUPPLY.

TO the "Suggestions" issued by the Local Government Board, and referred to by us last week, some useful appendices are added. We may more particularly allude to appendix E, on "Regulations as to House Fittings for Water Supply in the Metropolis settled by the Board of Trade." These regulations were made under the Metropolis Water Act, 1871, but are little known, and will be found of some value to other towns. We may specially draw attention to the thickness and weight of lead pipes for the conveyance of water, the weight per yard lineal being given. Thus, for pipe of 3in. bore, the weight is fixed at 6lb. per lineal yard; for 3in. 7/16in., for 3in. 9/16in.; for 1in., 12lb.; and for 1 1/2in., 16lb. per yard. We are not fully satisfied that these weights are adhered to in all cases, and we should like to know what test they are subjected to—if any—to ascertain if the pipes are of uniform thickness throughout. In frosty weather the constant bursting of pipes becomes a serious item to landlords or tenants, and, as the water rates are excessive, it is only just that the householder should be protected against the inconvenience and loss through inferior pipes being introduced. As regards "communication pipes," rule 5 makes it compulsory for every house supplied with Company's water to have its own separate pipe—except in those cases where a block of houses belonging to one owner is concerned, when, if not contrary to the special act of the Company, one sufficient communication pipe may be provided. Again, a very important regulation in respect of connection by "stop cock" is to the effect that every connection with the Company's pipes is to be "made by means of a sound and suitable brass screwed ferrule or stop-cock with union, and such ferrule or stop-cock shall be so made as to have a clear area of waterway equal to that of a half-inch pipe." How often this is overlooked, and again the next regulation that every external pipe shall be jointed with what is called a "plumbing" or "wiped" joint. It is surprising to find so many houses without that very indispensable addition of a stop-valve, which clause 12 states is to be fixed "at or near" the point of entrance of the communication pipe to the premises, or if desired within the premises. It is required to be of the screw-down kind with an area of waterway not less than that of 3in. pipe, or greater than that of the pipe itself. Coming to cisterns their accessible position for inspection, and cleansing, and covering are provided for, though how many we should like to know, even within the jurisdiction of the Metropolis Water Act, set this rule at variance? Again, in reference to draw-off taps, we may enter many houses and find them unsound or leaky; while in numerous closets (rule 20) that every boiler and w.c. "shall be served only through a cistern or service box without a stool cock" is not strictly observed. The fact is, many of the old fittings have been made to do duty. It is obvious, on reading these regulations, that good as they are, they have been made mainly in the interests of the water companies, and not altogether to insure the householder's convenience or to save his pocket, or we should have seen a more efficient regard paid to strong water pipes and the position and covering of cisterns—matters which at present may be found in every conceivable condition of unsoundness, neglect, and inefficiency.

For the first time during a period of thirty years Lord Pearlyn's extensive slate quarries in Carnarvonshire were on Friday last closed, directions having been given that, owing to the dulness of trade, the quarries, until further notice, will not be opened on Fridays and Saturdays. The like rule has been enforced at Mr. Assheton Smith's Llanberis quarries, and generally throughout the quarrying district.

The new Stock Exchange in Anglessea street, Dublin, was opened on Tuesday week. Messrs. Miller and Symes, of Great Brunswick street, were the architects, and Mr. George Meyer, LL.D., also of Dublin, was the contractor. The cost has been about £12,000.

OUR COMMONPLACE COLUMN.

FLUES.

FLUES for ordinary fireplaces need never be more than 9 in. square when in brickwork, or 9 in. in diameter when formed with pipes or in concrete. In open fireplaces the throating should be formed directly over fire-space, and kept as low as possible, so that the air passing up the flue may be heated. Flues should run direct to outlet, no bends being introduced with a less obtuseness than 130°, unless soot doors are provided. They should be rendered smooth, so that the smoke may ascend freely. Each fireplace should have a separate flue. They are best arranged in cross or party walls, and collected in a shaft springing from ridge, so as to preserve a uniform temperature in the flues, and prevent the smoke being chilled until it nears the outlet. For the same reason flues in external walls and in long shafts should have a thickness of at least 9 in. outside. A similar thickness is preferable inside, to prevent danger of firing floor or roof timbers. Flues should be carefully cored after completion, so as to remove obstructions. To prevent draughts the outlets from flues must be carried above the ridge, and not overtopped by adjacent buildings.—C. W.

FOLIAGE.

IN architecture and sculpture this holds such an important position that we have taken the liberty to extract at some length from M. Viollet-le-Duc. Before, however, doing so, it will be as well to enumerate what forms are chiefly used in English carving. These are:—Oak leaves and fruit, vine leaves and fruit, ivy, and herb benet. Under the title "Flore," M. Viollet-le-Duc gives in his "Dic. Rais." an elaborate and exhaustive article upon the subject. The following are translations of portions:—"We have often had occasion to speak of the flora of sculpture and architecture of the middle ages. It is, in effect, that architecture possesses its flora which modifies itself accordingly as art progresses and declines. During the Romanesque period the flora is but little more than an imitation of Roman and Byzantine sculpture; whilst there may be perceived, towards the beginning of the twelfth century in certain Romanesque buildings, a manifest tendency to seek the models of sculptured ornamentation amidst the plants of the woods and fields. But how did this research begin? To what elements does it attach itself at first? Who provokes it? How did it set up for a system to arrive at forming a school? It seems, in examining the monuments, that the monks (*clunisiens*) were the first to form schools of sculpture, going to search in natural productions the elements of their decoration. The capitals in the nave of the abbey church of Vézelay are no longer debased imitations of antique sculpture; their sculpture vegetation possesses a physiognomy which is natural to it, which has the crudeness of a new art rather than the barbarous impression of a died-out art—the reflection of traditions grown old. On the banks of the Loire, the Garonne, in Poitou, and in Saintonge, at the beginning of the twelfth century, may be seen sculpture sought from other elements than those left by antiquity. The attempts are always partial; they seem to belong to isolated artists, tired with always reproducing models of which they no longer conceive the meaning, because they were no longer acquainted with their origin." M. Viollet-le-Duc instances a capital from the abbey church of Boug-Dien, near to Châteauneuf (Déols), the sculpture of which dates from about 1130, and is based on the leaves of the brake (*Pteris*). "The sculptor here was neither inspired with Roman traditions nor with Byzantine ornamentation; he has gathered a sprig of the brake, has with curiosity examined it—he is enamoured with a passion for this charming production of nature, then he has designed his capital. The forms which the lay school adopt after breaking away from the traditions of the monks, the mouldings which they draw, the sections which they cut, and the ornaments which they sculpture, are based on principles foreign to Roman art. Examination and research replace tradition. When they have to do with ornament they no longer wish to look at the old capitals—Roman friezes—they go into the woods, into the fields,

they look amid the grass for the smallest plants, they examine the young shoots and buds, their flowers and fruit; and these are what, with their humble flora, compose an infinite variety of ornaments of a grandeur of style, a vigour of execution which leave far behind the best examples of Romanesque sculpture. Let it be instinct, let it be reasoning, these artists conceive that the smallest plants, like insects, are endowed with organs relatively much stronger than trees and the principal animals destined to live in the same midst. The forms of the smallest insects, like those of the smallest plants, have an energy, a purity of outline, a vigour of organisation which marvellously tend to express grandeur and force, whilst on the contrary one remarks, in the forms of larger plants particularly, a sort of indecision and weakness which could not furnish examples for monumental sculpture. Besides, who knows? These lay artists, who arose in France at the end of the twelfth century, and who raised themselves up in the midst of a badly constituted society, found perhaps a certain charm in enwrapping their art in mystery of the same kind that transmitted their grand principles to the shade of a sort of freemasonry. The first artists (we are speaking only of the lay school which arose from 1140-1180 in the Ile de France, and the neighbouring provinces), had devoted themselves to imitate the physiognomy of these modest field plants at the moment when they opened, when the leaves have scarcely sprung from their shoots or the buds appeared, when the thick stems, full of sap, have not attained their full growth, they had almost to seek as motives of ornaments the embryos, or even more, the pistils, the seeds, and almost the stamens of flowers. These were the elements with which they compose the lofty capitals which we admire around the choir of Notre Dame in Paris, in the church of St. Julien-le-Pauvre, in that of St. de Provins, at Sens, at Sens, at St. Leu d'Esserent, in the choir of Vézelay, in the church of Montreal, Notre Dame de Chalon-sur-Marne, around the sanctuary of St. Remi, of Rheims. Ere long they pass (for we know that these artists did not loiter on their way) to the imitation which develops itself. The stems grow longer and wither—the leaves open, the buds become flowers and fruit. Later on, these artists forget their humble primitive models; they go in search of their examples from the small shrubs; they select from the ivy, vine, holly, mallow, wild rose, and maple. At the close of the thirteenth century they begin to imitate servilely the oak, wild plum, fig, pear, as well as the leaves of the bindweed, parsley and herbaceous plants like the foliage of the principal trees of our forests. Everything to them is good—everything to them is a motive for ornamentation. Let us at once say that imitation approaches much nearer to reality as Gothic art tends towards its decadence. At the end of the twelfth century, and even to the beginning of the thirteenth, this imitation is submitted to monumental data, which lend to sculpture a particular beauty." "We may note that artists of the fourteenth century adapted the black hellebore (*Helleborus*), chrysanthemum, sage (*Grenadine*) strawberry, mallow (*Malva*), geraniums, ferns, large leaves such as the oak, maple, passion-flower, ivy, and vine. The sculptors of the fifteenth century adopted these that required more carving, such as the passion-flower, thistle, thorn, and mugwort (*Artemisia vulgaris*)." Amongst the illustrations of the above article, we noticed the following flowers were used in French sculpture. Birdfoot, trefoil (*Arum maculatum*), watercress, frogmouth (*antirrhinum*), liverwort (*Diclytra*), bryony, celandine, potentilla, plantain, birthwort (*Aristolochia*), violet sorrel, fig, and ferns.—C. F. W.

FONT.

The earliest font is supposed to be that in which Constantine is said to have been baptised—a porphyry labrum from a Roman bath. The Italian baptisteries were the first places used for immersion, and when the basilicas were converted to Christian use the baptistery was absorbed into them (instead of standing opposite the western entrance), and a font seems to have been placed within the western entrance from this time. Norman fonts are the earliest

in this country, and we may cite these in Winchester Cathedral and in the Church of St. Michael, Southampton, as two of the most ancient and interesting; they are of black marble, the bowl or basin being hollowed out of a square block, which is supported by a centre spiral shaft and four angle pillars. In both instances grotesque carving is found round the sides of the square top and on the top. By a constitution of Edmund Archbishop of Canterbury (A.D. 1236) fonts were required to be covered and locked, and the lids became at length very ornamental. The font is usually placed at the west entrance, either in the centre of nave or on one side. Sometimes a circular recess is built for it on the south side, or it occupies the tower. "J. A." cites fonts at Porchester Church, Lincoln, Lowestoft in Suffolk, Ludden in Norfolk, and East Dereham.

"E. W. P." mentions that a large one, of black marble, with twelve oxen rudely sculptured upon the outer face of upper portion of bowl, exists at St. Peter's Church, Ipswich. Another, of richly-carved Late Decorated character, adorned with representations of the Seven Sacraments, is to be seen in Rothwell Church, Northants.

"C. P. E." writes:—I omit all history of fonts, and merely call attention to a brass one in Munster Cathedral, described by Mr. G. E. Street and illustrated by him in the *Ecclesiologist*, Vol. XVI., 1855. It is supported upon five lions, two of which are standing, the others recumbent. The stem and bowl are circular, ornamented with tracery and mouldings; the bowl has five quatrefoiled circles, the eastern containing the baptism of our Lord, and the others the emblems of the Evangelists. Above them a trefoiled arcade contains half-figures of the twelve Apostles.

M. V. le-Duc, describing the fonts of the middle ages, says they are circular, square, lobed, or oval. They are ornamented with foliage, simple mouldings, figures, or geometrical designs, and are made of stone or marble lined with bronze or lead. The lids are generally of open woodwork, sometimes of open ironwork. Illustrations of the chief fonts are given in "The Architectural Antiquities of Oxford and Churches of Northamptonshire." There are casts of the following celebrated fonts in the South Kensington Museum:—Brass font in the Church of St. Bartholomew, Liege, made by Lambert Patras, 1112; 3 ft. diameter, and about 4 ft. high. Around the base are 10 cows' busts, the baptism of our Lord, the baptism of Cornelius by St. Peter, &c. Brass font in Hildesheim Cathedral; the basin is supported on four kneeling figures symbolical of the four rivers of Paradise—Geon, Phison, Tigris, and Euphrates. The ornament of the font is divided into four compartments—1. The Virgin enthroned. 2. Passage of the Red Sea. 3. Baptism of our Lord. 4. The ark being borne across the Jordan. Said to belong to the 10th century.—C. F. W.

Some of the plans submitted to the Town Council of Salisbury were last week severely criticised by that body. One of the councillors suggested that everybody appeared to be his own architect and draughtsman. Any one who saw the plans could hardly believe that there was a school of art in the city. The spelling was as bad as the designing. On a plan then before him "rope" was spelt "roap," "scullery" with a single "l," and "baroque" with but one "a." In some recent cases the plans submitted were so imperfect that members of the committee had to make personal visits to ascertain where the places were.

The Metropolitan Board of Works received at their meeting on Friday, two communications from the local authorities of Plumstead with reference to the disposal of sewage, and the all-god foul condition of the Thames. The district board of that parish wrote inquiring what step the Metropolitan Board propose to take in order to prevent the pollution of the river Thames by the sewage at present cast into it, and urging the necessity of adopting some system of deodorising the sewage and of utilising it in the cultivation of waste lands, and the vestry followed this up by a letter requesting information with regard to certain statements made at the Metropolitan Board on the subject of carrying the metropolitan sewage to the Maplin Sands, and the estimates for the work; and asking when the suggested scheme of utilisation and reclamation will be carried out. Both communications were referred without comment to the works committee, to be considered and reported upon.

THE USE OF THE HELIOTROPE IN GEODETIC SURVEYS.*

THE heliotrope is used to reflect the sun's rays to distant points, and thus facilitate the operation of reading angles, either horizontal or vertical, on lines of from 15 to 100 miles in length. The name is derived from *heli*, the sun, and *trope*, turning—hence the instrument is one which turns or deflects the rays in any required direction. It differs from the heliostat in not being automatic. Its construction is so simple that it may be made by any school-boy with a penknife. Two opaque screens are placed about 18 in. apart upon a strip of wood forming a base and screwed or nailed fast. A hole about 1 in. in diameter should be cut through each screen, the one in rear being a little larger than the other, and across each there should be drawn two fine wires or threads so as to intersect each other.

About 6 in. in rear of the screens there should be placed a small mirror—3 in. in diameter will be sufficient—so mounted as to have the two motions horizontal (or in azimuth) and vertical (or in altitude). The crude instrument is then ready for operation. To throw the ray upon any given object visible to the unaided eye, turn the mirror down out of the way or remove it altogether, and sight across the wires, moving the base until the line joining the intersections of the cross wires passes through the object. Then replace the mirror carefully so as not to disturb the line of sight, and turn it in either or both directions until the shadow of the edge of the hole in the first screen is concentric with that in the second. The reflected ray will then be visible to an observer at the given point. In the diagram S is sun, M mirror, S M incident ray, M N normal, and M R reflected ray.

When the observer is so distant that a telescope is necessary to determine the direction to him, the instrument is modified by attaching the rings and mirror to the telescope, care being taken that the axis of the rings is parallel to that of the instrument. Should the sun be in the plane of the mirror or back of it so that no reflection can be obtained, an auxiliary mirror must be used and placed in such a position as to reflect the ray upon the primary mirror which, by a second reflection, sends it through the rings.

Although so simple and inexpensive, this little instrument serves to increase greatly the economy and accuracy of reading angles to very distant objects. The rays reflected from it are plainly visible to the naked eye at from 30 to 50 miles, and with telescopes these "day stars" have been seen at a distance of nearly 100 miles across Lake Superior when no trace of land was visible.

It needs no second thought to perceive that they may be used as were the semaphores of Claude Chappé introduced in 1794 as the first efficient telegraph, but with greater effect. By adopting any convenient code of long and short flashes made by obscuring the ray, messages may be sent from point to point. In one instance a vessel was saved by signaling to a party at Marquette, Lake Superior, that she had grounded on some rocks near the station "Vulcan" on Keweenaw Point.

The Morse code is as convenient as any other, but for simplicity a conventional code expressing certain sentences by a few flashes is found to answer the ordinary requirements of field work.

The parish church of St. Mary, Thetford, Norfolk, was reopened on Friday, after the erection of a new roof. In the last Civil Wars the church was turned into a stable by the Parliamentarians, who pulled down the roof, but at the restoration it was replaced by the Corporation of Thetford, with the assistance of Thomas, Duke of Norfolk. It is this roof, which, having become insecure, has just been replaced. The new one is of pitch pine, with hammer-beam principals, resting on moulded stone corbels, with traceried spandrels and boarded ceilings, and is covered with slates and red ridging from Maidenhead. There are also new stone cornice, stone coping to chancel gable, &c. The work has been carried out from the designs of Mr. E. Beardman, of Norwich, at a cost of £470. Mr. S. Holden, of Thetford, was the builder. In the spring time the porch is to be restored by the same architect and contractor, at a cost of £85.

* By L. M. HAUPT, Professor of Civil Engineering, Towne Scientific School, in *Journal of Franklin Institute*.

Building Intelligence.

CORK CITY.—The Earl's or north transept of the new cathedral of St. Finn Barre has been enriched with several stained-glass windows, so that when the works in progress are completed there will remain but two plain windows in the transept—those in the ambulatory. The principal window is a rose, lately set up to the memory of Francis, third Earl of Bandon. This consists of eight compartments round a figure in an oval. The central light represents our Lord on a blue ground, seated on a rainbow in a silver halo; the other lights depict the different scenes from the scriptural narrative of the Resurrection, and treat the condition of the blessed and those who have not attained to so high a state of happiness hereafter. The four windows beneath will be appropriated:—No. 1 as a memorial to the late Earl of Carlisle; No. 2, by the Duke of Devonshire; No. 3, by Sir Arthur Guinness; and No. 4 to the memory of the late bishop, Dr. Gregg. In the ambulatory is the Countess of Bantry's window. The three lights represent "The Flight into Egypt," "The Slaughter of the Innocents," and "Jesus Discouraging with the Doctors in the Temple." Near by is another three-light window to the memory of the late Recorder of Cork. The subjects are:—"The Shepherds and Angels in the Field," "The Shepherds Worshipping the Holy Child," and "The Adoration of the Magi." In the north aisle are a series of windows filled with the following subjects:—"Abraham Entertaining the Angels," "Abraham about to Slay Isaac," "Moses and the Burning Bush," "Judgment of Solomon," and "Solomon Building the Temple." The choir wall has been presented by Mrs. Elizabeth Gregg. It is 4 ft. high, composed of white-veined marble, with three moulded panels, two containing foliage, and the central one a grotesque human head of alabaster on gold mosaic ground, set in frames of green Galway and red French marbles. The base and capping of the walls are moulded, and the cap is set with alternate slabs of red and green porphyry, between intermediate squares of lapis lazuli and bezants of gold mosaic. A border of gold mosaic is set round the entire of the cap. The inside of the wall facing the chancel is of the same marble, with square panels of red and green alternately. The choir gates, given by the Countess of Bantry, are 6 ft. 11 in. wide and 4 ft. high. They are of polished brass, and each gate contains nine panels; those in the centre are composed of quatrefoils and birds of paradise, the others of quatrefoils with tracery, foliage, scroll-work, and birds. The new lectern has been given by the women of Cork city and county, and has been wrought in brass, at a cost of £220, from the designs of Mr. W. Burges, the architect of the cathedral. It is 9 ft. 9 in. from the ground, and stands on a square pedestal, supported by four lions' paws resting on circular bases. The pedestal tapers from 2 ft. 1 in. to 1 ft. 5 in., and is 2 ft. 2 in. in height. Each of the four sides is decorated with Early English foliage, which springs out of animals' heads, in which five crystals are set. On the top of the pedestal is a circular base 4 in. in height, which supports the pillar, which is 2 ft. 2 in. high. In the centre of the pillar is an annulet set round with 16 crystals, and on the top a cap set with 48 crystals in double rows of triplets each. From this cap rises a triangular revolving desk. On one panel is a profile of Moses, on the other that of David, in alto relievo. On each side are elaborately-ornamented bracketed sconces, and on the top of the desk is a cresting of interlaced foliage. The leaves are surmounted at the apices by crystal globes.

NORTHAM parish church, East Sussex, has just undergone extensive internal restoration. The exterior had been previously restored and enlarged, and the spire rebuilt and raised 10 ft. from the designs of the late Mr. Sydney Smirke, R.A. The present works include the taking down of the galleries and the removal of the fine organ after alteration to the north chancel aisle. The flat ceiling of the nave has been cleared away, showing the old timbered roof. New roofs have been placed upon the north and south aisles, the plastering knocked off, and the walls stuccoed. The whitewash having

been cleansed from piers, arches, and windows, the masonry is seen to be from local quarries. The old square pews and nave and nave aisles have been replaced with open benches of pitch pine and oak. A glazed oak screen has been placed on the east side of the tower arch. The passages of the nave are repaved with tessellated, and those of chancel with encaustic tiles. During these operations a stoup was discovered close to the entrance to the south aisle, and also a piscina in good condition. At the east end of this aisle the windows have been restored and filled with cathedral glass, and a bed of concrete spread over the ground beneath the floor. A large vestry has been erected, and warming apparatus introduced into the church. The present work has been carried out at a cost of £1,100, from the designs of Mr. Albert Smith, architect, of Rye.

STAINED GLASS.

BROOMFIELD.—A stained glass window has been placed in the west end of the north aisle of Broomfield Church, near Chelmsford, as a gift by Mr. Clayton, of the firm of Clayton and Bell, in memory of the late vicar, the Rev. J. P. Smith. It is in three lights occupied respectively by the full-sized figures of Noah, Moses, and John the Baptist; the tracery above of decorated character contains some texts, and at the foot is a dedicatory inscription.

WATER SUPPLY AND SANITARY MATTERS.

ALFRETON.—Owing to pit workings in this neighbourhood the supply of water for some years has been growing deficient, and the Belper rural sanitary authority are taking steps to alleviate the water famine. Messrs. Coke and Mills, of Chesterfield, are the engineers, and they have decided to obtain water from Lindway-lane and Butterley, a distance of 5 miles from Alfreton, and so much above the town level that the water can be conveyed by gravitation. Two reservoirs are being constructed by Messrs. T. and F. Coulton, of Birmingham, one of which, at Lindway-lane, covers an area of 8 acres, and another still higher at Butterley, near Ashover, covers rather more than an acre. The contracts, which amount to upwards of £18,000, should have been completed by August, 1879, but owing to unforeseen difficulties having intervened it seems very improbable that the works will be finished by that time. Messrs. Oakes, of Riddings, supply the cast-iron pipes, and Mr. Thos. Cramp is the contractor for laying them down.

New Board schools were opened on Monday last, in the district of St. Augustine's, Norwich, to accommodate 1,250 children. They were built by Mr. Youngs, of Norwich, from designs by Mr. John H. Brown, architect to the board. No expense has been spared in building and fitting these schools with the newest and most approved appliances. This portion of the work was entrusted to Mr. G. E. Hawes, of Norwich, who has supplied all the fittings throughout. The boys' and girls' schools are supplied with his celebrated "locker deal desks."

The parish church of Hopton, West Suffolk, is about to be restored at a probable cost of £1,200.

On Tuesday week Mr. Loomes, builder, of Belper, the contractor for the erection of a new Wesleyan school-room in the Pottery, Belper, was assisting in putting a stone in position when the scaffolding gave way, and he fell, with the stone upon him, and was seriously injured.

The Queenstown Town Commissioners have received the sanction of the Public Works Loan Commissioners for loans of £1,300 for making an approach to boat harbour, making hydrants, flagging streets, and making boundary road walls, and £100 for sanitary purposes.

The twentieth annual dinner of the Nottingham Operative Painters' Society was held on Saturday evening, at the Punch Bowl Inn, in that town, Mr. Southgate in the chair.

The De Lank Quarries Company, near Bodmin, have received an order from the Trinity House Commissioners for £20,000 worth of granite, for the construction of the new Etdystone Lighthouse, and a tramway four miles in length is to be made to Bodmin-road station to ship the same. The granite used in the new General Post-office and for the Victoria Embankment quay wall also came from the De Lank quarries.

At the Norfolk Quarter Sessions, last week, it was reported that extensive additions were being made to the county pauper lunatic asylum from the designs of the county surveyor—Messrs. Cornish and Gaymer, of North Walsham, being the contractors. £13,000 has been expended on the work, and £9,000 more was asked for (and voted) to complete the work.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post-free 2½d. Office: 31, Tavistock-street, Covent-garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold); To France or Belgium, £1 6s. 6d. (or 33fr. 30c.); To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted, some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charge being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

"BUILDING NEWS" DESIGNING CLUB.

SERIO MELIORA. (You say we have not understood the meaning of your drawings. If the corbel in detail was a stone one so much the worse, as our remark in that case applies with greater force. What we criticised was the extraordinary profile.)—A. BANKS. (The rules are not published separately, but the number may be had on enclosing stamps.)

OUR COMMONPLACE COLUMN.

NOTES or quotations upon subjects under the heads of French casement, gable, Galilee, gallery, gate, gauge, gauged arch, geometric proportion, Geometric Decorated, gilding, girder, glass, Gothic, granary, granite, Greco-Roman, greenhouse, &c., will be received up to Tuesday, the 21st inst.

Correspondence.

BELHAVEN CHURCH, GLASGOW.

To the Editor of the BUILDING NEWS.

SIR,—There can be no doubt that the designer of the above church is a great admirer of the works of Mr. Norman Shaw; and that there is a great similarity between Belhaven Church and the English church at Lyons a glance at the lithographs, as your correspondent has pointed out, will show. This I had previously noticed on seeing the drawing in the Academy last year.

But are Messrs. Campbell Douglass and Sellars to blame for making their church so close a reproduction of one of the best works of one of our most celebrated architects? We all like originality in architecture when it produces a beautiful design and a building that it is a joy to look upon, as evinced in so many instances in Mr. Shaw's work; but where that originality in design is lacking, I think, as our architectural friends from the North appear to have done, that it is better to perpetuate a good thing than perpetrate a bad one. And I say this not in disparagement of Messrs. Campbell Douglass and Sellars, for I have no doubt that Mr. Shaw has in his time been indebted to old work for ideas and for the contour of his mouldings, not fearing to reproduce them in his new work because they were copies of the work of our glorious old monk architects.

Your correspondent, "Wykeham" seems by his taking this matter up, to infer that architectural plagiarism is something new, and, moreover, a very heinous offence; but where is the architect amongst our teeming thousands who, when the question is asked, "Didst thou do it?" can stand forward and unblushingly say "Not guilty?"—I am, &c.,

HENRY HOPTON.

THE BALLOT AT THE A.A.

SIR,—I objected to the ballot for the reasons stated in my letter of 27th December, and I do not admit Mr. Scott's conclusion that the general objections to the ballot are exploded. I esteem it an honourable distinction to belong to the minority who condemn it.

I have not disputed the right of rejecting candidates for election. I agree with Mr. Scott that the reference of the name of an applicant to the committee should insure such inquiry that there should be no question of his fitness, but I am not of opinion that our delegation of such power to our committee should do away with the ultimate appeal to the whole body of members. Our franchise applies to more than election of members, and is a right which we should guard. As to whether "a pupil who has been only a month in an architect's office" is competent to decide upon the merits of a candidate, I believe that the intelligence of the class from which our pupils are drawn is beyond the average, and I think he is as capable under such simple circumstances as the older members. In the case of any candidate the persons who have special knowledge of him are few. The election simply gives them an opportunity of expressing their dissent, and theirs are the only votes of any special value; the others are the result of confidence in the committee or otherwise. If the conditions of membership become more clearly defined, and the committee are careful in their inquiries, we shall hear no more of the election of unfit persons.

Mr. Scott tells us that the junior members obtain the largest share of the advantages of the association, and so they should. The association was instituted for the pupils and obscure men, not for "the practitioners of 40 years' standing." I believe that the senior men who have done so much for the association are contented with the approval of their own consciences and the satisfaction of leaving the profession better than they found it.

If the line of separation between the pupils and the 40 years men does exist, the sooner it disappears the better for every one concerned. We all admit that the general status of the profession requires to be raised. The association should be a powerful element in this work, but any result worth the having will only be brought about by the co-operation on equal terms of the whole body of the members. Our like profession should be a warrant of equality. If the members of the association tolerate the institution of a superior order and the deprivation of their right of voting, they are a much more spiritless body than I have supposed.—I am, &c., JOHN LEANING.

SURVEYORS' FEES—QUALIFIED SURVEYORS v. QUACK MEASURERS.

SIR,—Having had nearly forty years' experience as a contractor for works in various parts of England and Wales, I have been much interested and amused by the varied experiences of your correspondents during the last few weeks. There is, in my opinion, much to add to what has been already stated, and in justice to the bona-fide and duly qualified quantity surveyors, all the odium attached to the subject should be removed from their shoulders and placed to the credit, or rather discredit, of the wretched quacks (and their name is legion) who palm themselves off upon architects, builders, and the public as surveyors, when utterly incapable of performing the duties they undertake.

In my experience the overcharges, tricks, and errors of which builders and others justly complain are the work of the impostors I allude to, while such men as Rickman, Poland, Gardner, Son, and Theobald, and numerous others in London, and a few in the provinces, are incapable of the errors and charges of such

men as I refer to, their work being at the same time thoroughly well done to the satisfaction of all parties concerned in contracts.

The delinquencies of unqualified surveyors have not been fully stated by any of your correspondents. I can, from my own experience, give numerous cases in which great frauds have been committed, while the helpless client is kept in ignorance of the facts by clever manipulation of the accounts to "blind" him, and the contractor is made the medium or instrument of such architects and surveyors in abstracting from the client's pocket large sums of money to transfer it to the architect's pocket in the name of fees. To illustrate this part of the subject I give a few cases within my own knowledge:—

1st. An architect undertook to build two houses exactly alike for £2,500 or £1,250 each. In due course tenders were obtained, based upon the architect's own quantities of one building only, for which he charged 2½ per cent., with the addition of £23 for copying (four copies), at the same time instructing the builder to double the amount of his priced estimate as a tender for two buildings. The lowest tender amounted to £3,800 instead of £2,500, the charge for quantities being £140. The client thereupon refused to build unless the tender could be reduced to £2,800. Subsequently the architect submitted to the builder an offer of the reduced amount for an amended design without taking quantities, but to include the fee of £140. The work proceeded, during which trifling changes were made, involving extras of about £200, but the architect, instead of measuring the extra work, which could easily be done, made a bill of extras and deductions of a very large sum, added the two together, charging 2½ per cent. again on the result. The most barefaced wrong of all was the fees charged on what are termed provisions, which for grates, &c., were put down at about £300. 2½ per cent. was charged in original quantities, and again on both sides, extras and deductions, amounting to 7½ per cent. in an item that involved no measuring, designing, or selection, the client having purchased the goods himself. The "copies" of quantities were charged £46, whereas they would have been amply paid for at £1, being written at one operation on tissue paper through carbonic sheets.

2nd case. A client requiring additions to a house consults his architect, expressing his intention to spend about £4,000 on this basis; his architect prepares plans and issues his own quantities, and the lowest tender amounts to about £10,000. 2 per cent. and a fee for copies is charged on the £10,000, and the usual process of reduction takes place in order to induce the client to build; quantities are again taken out, and another commission charged, the tender being £5,000, for which sum a contract is made, the architect being paid nearly £300 for quantities on £5,000 contract. In this case a large sum is put down for provision for contingencies, on which the architect charges measuring commission four times—viz., 2 per cent. originally, 1 per cent. on second tender, and he includes the item on both sides, extras and deductions, charging commission again and again.

In the latter contract the architect proved to be utterly incompetent either to take off quantities or measure work when done.

I can give scores of similar cases in which builders are to a certain extent involved, but for reasons you can understand are powerless as individuals to reform such transactions. I would suggest and urge upon the leading associations of both architects and builders to take this matter up and devise some means of supporting and encouraging only such surveyors who are properly educated to the work, and ousting from practice all such impostors who, without the necessary knowledge and experience, foist themselves upon the public as surveyors.

My experience leads me to the conclusion that properly qualified surveyors cannot afford to risk their reputation by resorting to such practices as I allude to, but that ignorant inexperienced men snatch every opportunity that offers to swell a precarious income, trusting to the secrecy that builders are bound to observe assisting them to extract unearned money from their clients' pockets.—I am, &c.,

AN OLD BUILDER.

Intercommunication.

QUESTIONS

[5629].—**Fir.**—How can one distinguish between Swedish and Memel or Riga fir, when cut into scantlings? An answer will oblige.—H. W.

[5630].—**Inscription.**—Would some kind reader furnish me with the meaning of the following sentence which I find engraved at the bottom of several monumental brasses—"Cujus A'is p'picietur dens?" Another form thus—"Cuj aie p'p'iet' de'."—A. B.

[5631].—**Sketching.**—I purpose devoting four or five weeks next summer to sketching mediæval work in some one English county—I am indifferent which. Will some one kindly advise me which to select—as presenting the most fruitful field of study?—J. W. W.

[5632].—**Right of Access.**—A piece of land has been left to me and a few relatives, to be divided amongst us, which, if divided as set forth in the will, leaves me with a piece of land without any way of getting to it from a public thoroughfare, as it is behind other property. Will some of your readers kindly favour me with their opinion as to what course I am to take in order to get access to it, and oblige—A CONSTANT READER?

[5633].—**Roof-Tiling.**—Would some reader kindly say what is a fair price per square yard for flat red Staffordshire roof tiling in Yorkshire, including both material and labour, and also what is the best way of fixing tiles?—C. S. M.

[5634].—**Strength of Roof Materials.**—I wish to calculate for and find out the strengths of rafters and struts for iron roofs, but am at a loss with the rules I have, which are from Spon's and Hurst's tables. I can find out what weights they will have to sustain by the triangle of forces, but not the sections of metal to sustain these weights. If some reader will mention some works treating on the subject—not algebraically—or give some information through the medium of your paper, I shall be obliged greatly.—AMATEUR.

REPLIES.

[5624].—**Tiled Roof.**—The lap is always considered to be from the pin or nail hole to the outer lower edge of the "overlapping" tile or slate.—B.

[5625].—**Rendering Wood Incombustible.**—One means of rendering wood unflammable is by steeping in or washing it with alum water. This should be frequently repeated. There are other processes, but this is the cheapest. Of course this does not render wood incombustible, and I am not aware of any process that does.—G. H.

[5626].—**Hollow Walls.**—My experience is that it is best to place the 9in. inside to carry the weight of floors and roof, and to build the 4½in. all stretcher bricks, bonded with iron ties forked at each end, and with a twist in the centre to prevent the water drifting. These should be made hot and dipped in gas tar. Timber framing should be grooved on the edges next the bricks, say, 1½in. wide and 1in. deep (vertical timbers only), and if cemented a taper groove in addition for the cement, which should be flush with timbers.—JAMES THORNELOE.

[5626].—**Hollow Walls.**—I have generally placed the 9in. wall on the outside, as it forms better reveals for the openings, the 4½in. answering very well on the inside and for taking the bond timber and joists. I should certainly advise "W. R." not to trust in the tile hanging outside a half brick wall to keep it dry. There should be a hollow space and inside battening. Cement and plastering may do a great deal but they will not keep a 4½ solid wall dry under ordinary precautions. "W. R." will find in a recent

volume of BUILDING NEWS a section of a half-timbered wall.—G. H. G.

[5627].—**Fir Timber.**—The term "fir" is rather a general term used to mean Baltic timber. It is certainly vaguely applied, and may mean spruce as well, but used in the sense referred to after the specification of Baltic red wood, it can only apply to that kind of fir timber.—AN ARCHITECT.

[5627].—**Fir Timber.**—The term "fir" in bill of quantities is not to be literally taken as understood in the timber trade, to which your correspondent appeals. It is a general term for fir, deal, or pine, and the like. Similarly, it is common to talk of deal boards, deal doors, and wrought deal for wood that is not deal. Fir framed in roofs, rough fir in lintels, fir in joists, &c., would include Baltic or other pine or fir, for which the specification must be referred to and followed. The definition may be somewhat loose, but it is well understood technically by all builders and surveyors. It would be the veriest quibble to treat the term apparently in its narrow sense so as to make it include the cheap rubbish answering to the name.—B.

CHIPS.

The drinking fountain erected in memory of the late Mr. Samuel Turner, at Buxton, was unveiled on Wednesday week. The work of erection and carving was carried out by Mr. Ash, monumental sculptor, of Buxton.

A new stry factory, built for Messrs. Footman and Co., in Tavern-street, Stowmarket, was opened a fortnight since. Messrs. Andrews and Son, of Stowmarket, were the builders.

An experiment in providing improved dwellings for the very poor has been made at Launceston with success by Colonel Deakin. Two blocks of eight cottages each, of stone, with slated roofs, have been erected on the Launceston-road. Each cottage contains four rooms—two on ground floor and two above—with lean-to at rear and a small garden, and lets at £4 per year. It is said that at this moderate rental they will yield 5 per cent. on the outlay. Mr. Thomas Longman was the builder.

Extensive repairs are being made to Cattawade-bridge, over the Stour, connecting Suffolk and Essex at Manningtree, under the superintendence of Mr. H. M. Eyton, county surveyor for Suffolk.

The Leeds Town Council have raised the salary of their gas engineer, Mr. Woodhall, from £500 to £650 a year.

The Dover Town Council and Harbour Board have completed a scheme of sea defences at East-cliff, and on a portion of the Esplanade, under a local Act of Parliament. The contract was carried out by Mr. Josiah Hall, of Queenborough, at a cost of £9,500, and under the supervision of the borough surveyor.

The town council of Preston have accepted the tender of Messrs. W. Allsup and Sons for the supply of ironworks, &c., for additional cattle pens and gates at the cattle market.

It was reported to the Bathual-green guardians on the 31st ult. that the works at the well on the workhouse premises had been stopped by the contractors (Messrs. Doe and Co.), as in their judgment the object desired had been accomplished. The boring had been carried to a depth of 30ft. from the surface, and a supply of water had been obtained which seemed practically inexhaustible. Satisfaction was expressed at these statements, and pumps and other fittings were ordered to be erected forthwith.

Our Office Table.

A WELL-KNOWN architect, one of whose buildings was illustrated in our Christmas double number has, to his surprise, received from some outsider an offer of fifty copies of the drawing. We have made inquiries, but cannot find the individual from whom the offer emanated. Unless the copies referred to were bought in the ordinary way with copies of the paper from our publishing office they must either have been surreptitiously obtained or reproduced—probably in some inferior manner—without our authority, and at the risk of legal proceedings which we should of course be compelled to take against any one infringing the copyright of the authors of drawings reproduced by us, or of our right of illustration. Architects and others will therefore do well in any similar case to refuse to entertain any similar proposals, and to inform us at once if any such offers are made to them.

The following schedule of prices for well-sinking in clay, lined with 9in. brickwork in Portland cement, are given in the revised "Local Board Suggestions," and may be found of service:—

Wells of 4ft. diam. to depth of 200ft.,	50s. per ft. run.
" 5ft. " " " "	65s. " "
" 6ft. " " " "	85s. " "
" 7ft. " " " "	105s. " "

In chalk the prices without brickwork and pumping are, for—

Wells of 4ft. diam. to depth of 200ft.,	18s. per foot.
" 5ft. " " " "	24s. 6d. per foot.
" 6ft. " " " "	27s. 6d. " "
" 7ft. " " " "	35s. " "

Of course, the above prices will vary according to district and other circumstances.

MANY schemes have been propounded for uniting the Cheshire and Lancashire sides of the river Mersey, but up to the present they have all failed. Another scheme is about to be laid before the public, and from the approval which it met at the hands of many of the leading merchants, shipowners, and others, at a private meeting held in Liverpool on Monday, there appears to be some prospect that it will be launched under favourable auspices. Mr. C. G. Mott is the originator, and from his explanation, it appears that it is proposed not to have a railway tunnel, but one for pedestrians and vehicular traffic. As the gradients required for this tunnel can be made much more steep than for a railway tunnel, it will be unnecessary to carry the approaches so far into either Liverpool or Birkenhead as it would be in the other case. The proposed works would commence opposite the open space in front of St. Nicholas's Church, then make a detour to the left, and pass underneath the Chester Wharf, and the entrance to the Manchester Dock. It will then cross underneath the river, come out near to the Morpeth Branch Dock, and be brought into direct communication with Argyle-street, Birkenhead. The tunnel is to

OFFICE ON THE WORKS, KEYMER JUNCTION.

be a double one, with two arches, each arch having a footpath for pedestrians, a tramway road, and two lines for carriage and cart traffic, making in all three lines of road in each direction, in addition to the accommodation for foot passengers. As the bottom of the river is composed of solid sandstone rock, no engineering difficulties are likely to be encountered, and there will, it is expected, be little trouble in keeping the place free from water. The total length of the roadways will be one mile and a third, and the entire cost is estimated at £300,000 to £400,000.

MR. WHISTLER, having failed to get satisfaction out of Mr. Ruskin in the law courts, has published a pamphlet, which he dedicates to Mr. Albert Moore. He declares that the war, of which the opening skirmish was fought at Westminster, is really one between the brush and the pen, and he refuses to acknowledge Mr. Ruskin as a competent critic. Mr. Whistler is not content with merely flagellating Mr. Ruskin. He attacks all art critics, and maintains that they should be extinguished, and that they have no right to carry their praise or censure into the domain of art. Whatever may be said of his painting Mr. Whistler proves that it must be better than his writing, and that both are better than his taste. Thus, he writes of Mr. Ruskin, in his capacity of Slade Professor, as "whining for pupils." Again, writing of the author of "Modern Painters," and with an obvious reference to that work, he says, "Let Mr. Ruskin resign his present professorship to fill the chair of ethics at the University. A master of English literature, he has a right to his laurels, while as the populariser of pictures he remains the Peter Parley of painting."

HELLIWELL'S

Patented New System of AIR AND WATER-TIGHT IMPERISHABLE GLAZING.

All woodwork is covered, and no outside painting is required. Old Roofs re-glazed. Any one can repair or take in pieces.

"It is suitable for Railway Stations, Mills, Weaving Sheds, &c., but is specially applicable to Conservatories, Plant Houses, and Orchard Houses, and we should be very much inclined to try the system. It is certainly worth looking to."—*Builder*.

"And will, in our opinion, supersede any other similar system before the public."—*Building News*.

"It seems to meet the end in view more nearly than anything we have seen yet."—*The Field*.

"The patent has given high satisfaction to every one using it."—*The Christian Union*.

"Convincingly prove the new Glazing System to be worthy the attention of readers of the *Keystone*."—*The Keystone*.

WAGES MOVEMENT.

LEEDS.—The Leeds Master Builders' Association has given notice to the operatives in the various branches of the building trade in Leeds and district for a revision of the present wages and working rules, the main features of which are contained in the following memoranda:—Masons: Notice given October 21, 1878, to expire 1st May, 1879. The present rate of wages is—setters of stone, 9½d. per hour, to be reduced to 9d. per hour; the present rate for masons is 9d. per hour, to be reduced to 8½d. That walking time, lodgings, and railway fares be matters for arrangement between employers and operatives. The masons now commence work on Monday morning at 8.30 o'clock. It is proposed that they shall commence at seven o'clock, the same as the other branches, and that on Saturdays, instead of giving up work at 12 o'clock noon, they shall work until 12.30. Bricklayers: Notice given to bricklayers October 21, 1878, to expire 1st May, 1879. That the question of walking time, lodgings, and railway fares be matters for arrangement between employers and operatives. Labourers: Notice given October 28, 1878, to expire 1st May, 1879. There is no existing code of rules for labourers. They are receiving 6d. per hour at present, and work 50 hours per week. It is proposed that they should be reduced to 5½d. per hour. Joiners: Notice given December 27, 1878, to expire 1st July, 1879. Joiners' present rate of wages is 8d. per hour; to be reduced to 7½d. per hour. That the question of walking time, lodgings, and railway fares be matters for arrangement between employers and operatives.

MONTROSE.—After a strike of six weeks' duration, the masons in Montrose have accepted the masters' terms—viz., 6d. per hour for shed work, and 6½d. for work not under cover, the three months' notice on either side being abandoned.

SHEFFIELD.—The master builders of Sheffield held a meeting on Thursday night to discuss the position taken up by the masons. It was unanimously decided that the masters should stand by their original decision—in other words, that they should not give five months' notice of their intention to reduce the wages of the masons. It was emphatically denied that any rule existed by which they were compelled to give five months' notice, it being stated that they had not signed any rules since the last strike, and that a rule requiring five months' notice was therefore not in existence. It was further stated that the masters had given the joiners six months' notice of a reduction, because they had signed the rules of the Joiners' Association, which required that such notice should be given.

WESTON-SUPER-MARE.—The carpenters' strike in this town was brought to a close on Wednesday week, when the men gave way, and agreed to go in on the terms of the masters, whose sole object has been to secure uniformity in the working hours of the several branches of the building trade. Work has been by no means brisk in Weston, and many of those who had been receiving strike pay have found their places occupied by strangers.

YORK.—At a meeting of the operative bricklayers of York, held on Saturday night, it was resolved to accede to the masters' proposal of a reduction of ¼d. per hour.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.

Agent: Mr. E. CRICKMAY, 4, Agar-street, London, W.C.

TENDERS.

BIRMINGHAM (OLTON).—For a villa, including greenhouse, &c. Mr. Ewen Harper, architect, 27, Bennets'-hill, Birmingham:—

Lidzy	£1,261
Briley	1,240
Lee	1,147
Mills & Son	1,177
Dowse	1,135
Freeman	1,110
Wheeler	960

BOURNEMOUTH.—For a spire to the parish church of St. Peter, Bournemouth. Mr. G. E. Street, R.A., architect:—

Stephens & Barton, Bristol	...	£2,999
Dove Brothers, Islington	...	2,967
Adamson & Sons, Putney	...	2,965
Clarke, S., Bournemouth	...	2,946
Wall & Hooke, Brimscombe, Glo's.	...	
(accepted)	...	2,560
Pearce, Jas., Eastbourne	...	2,051

BRAY, CO. WICKLOW.—For the formation of a drain from Christchurch-terrace to the Bray main street for the Bray Town Commissioners. Mr. Brett, C.E., engineer:—

Brady, B. (accepted)	...	£557
----------------------	-----	------

[Lowest of four tenders received.]

DURHAM.—For the erection of a new central police-station for the county of Durham, at Durham. Mr. William Crozier, M.I.C.E., architect; Mr. James Greenwood, quantity surveyor:—

Caldclough, Durham	...	£3,519 0 0
Lowes, Durham	...	9,450 13 9
Gowens, Hebburn	...	9,272 9 9
Forster, Croxdale	...	9,037 3 6
Robson & Son, Durham	...	8,997 0 0
Kennedy & Son, Jarrow	...	8,985 7 7
Inglis & Reah, Middlesbro'	...	8,958 0 0
Whaley, Durham	...	8,871 9 4

THE BUILDING NEWS.

LONDON, FRIDAY, JANUARY 17, 1878.

DISCOVERIES IN CYPRUS AND ASIA MINOR.

THE world of art and archaeological discovery promises to be opened up in Cyprus and Asia Minor consequently upon recent events. In the island researches have already been commenced for the twin of that famous Phœnician idol in the Louvre, at Paris, wearing a crown of gold, ornamented with flowers and stars, with a collar on her neck, and her hands in the attitude of the Medicean Venus. So far, however, the new researches have gathered no fruit; and it is among the architectural remains of the region now given up to English protection, with the illustrations of artistic and domestic economy belonging to them, that the richest treasures are hoped for. These have been undertaken, indeed, by many of the same hands which produced the admirable restorations of the Roman and Augustan temples, and those in Arcyra and Galicia. We have thus found ourselves the heirs—or, rather, perhaps, trustees—of a prodigious antiquarian inheritance, which we shall have to guard against desecration and despoilment, together with rock and tablet inscriptions of Scriptural import, the transcripts of which have yet to be given to the world. These, we are told, reach to lower depths by far than those of authentically recorded history—beyond the apocryphal sandals of the Thothmes, and further even than the decorations on the undated tomb of Rehhamah, to which, nevertheless, an epoch must be assigned. The archaeologists at present at work, however, while searching for the traces of cities, temples, and other edifices, have been content, of course, with such as they are discovering upon or near the surface—slabs of stone engraving, with designs of heavy-wheeled chariots, drawn whether by oxen or horses, such as are described in the Trojan epic—shields and circular buckles, and short double-edged swords. Where these are found—and they are being found in rapid succession just now—it is evident, at least, that battles were fought, and battles in those ages were generally fought in the vicinity of populous places. Without troubling themselves upon these points, however, the latest excavators of Cyprus and of—as it were—Europeanised Asia Minor content themselves with chronicling the earlier results of their researches. It is thought that by means of these, and the results which will probably be gathered after them, a clear affinity may be traced between, for example, the relics dug up in the Etrurian necropolis of Vulci, and a large class of the Ninevite remains, between the Etruscan vase and the Assyrian or Babylonian cylinder. Should this be done the key to a great mystery will have been turned, and the traditions of the potters and painters belonging to the times of Candulus and Croesus be traced, both forwards and backwards, at once to their origins and to their influences. Even now some objects of Assyrian manufacture have been unearthed, bearing a wonderful resemblance to the gold cups disintombed from the sepulchres of Ceri, with bases characterised by every attribute hitherto assumed to be essentially and uniquely Greek. Should the process go on, with like results—for up to now our archaeologists have been only scratching the surface—a new point of departure, almost, will have to be, upon these lines of inquiry, fixed. The whole subject, however, is of interest, and especially to those who have confined their speculations, for the most part, within the limits of the Layard inves-

tigations. Even our sappers and miners, turning up the soil for the sites of encampments and barracks in Cyprus, hit upon winged figures, bull-shaped forms with humanised faces, griffins, and creatures with fish or reptile tails—imported from the mainland, no doubt, yet none the less suggestive of curiosity on that account. We have, in fact, in this part of the East stumbled among the materials of a perfectly new museum. Together with these have been “finds” of ironwork, gold, ivory, and glass, to which as yet no positive period of manufacture can be attributed. They are distinguished, says the correspondent of a French academical journal, by the fact of their possessing no typical, or, at any rate, known characteristics whatever. But, at a first glance, the fresh discoveries reported from Cyprus, and from Larnaca, the ancient Kittium, in particular, may be described as of supreme interest. They consist, for the most part, of gold, silver, and bronze cups, similar in design and craftsmanship to some which have been for many years exhibited in the archaeological galleries of the Louvre, in Paris. In addition, however, to the vases in metal, are those in painted earth, having a strong resemblance to others brought from Italy, and from the Valley of the Tigris as well, without any historical relation having ever been critically established between the two artist races. They are precisely the same as those which adorned the tombs of Asiatic kings and the temples of Greek Pagans. But they are more than this. The fragments disintombed, as it were, yesterday, correspond in all essentials with that celebrated pottery of the Cyclades which commanded the art-markets of Europe down to the twelfth and thirteenth centuries of the Christian era, and which had no other decorations than triple-coloured stripes, plain zones, zigzags, and circles, with a bistre tint, on a grey or yellow ground. These were varied occasionally by conventional roseate forms, figures of plants and flowers, animals arranged in long processions, monsters—half-human and half-bestial—sphinxes, syrens, and the subjects of an uninterpreted mythology. The similitudes of these, be it remembered, are now found, as they were found at former dates, not merely in the Isle of Cyprus itself, but also in the almost continuous region of Asia Minor. They include, moreover, representations of tapestry and other woven work, with apparently Oriental borders, the origin of which must remain a perplexity to all except the most courageous antiquarians. Still, the Cyprian vases would appear to possess a distinctive character in so far that, while decorated, in common with others, with girdles of engraved figures, frieze-like in their arrangement—to employ the term not in an architectural sense—the engraving is rarely in relief, while the modes of composition—and this completely accords with what we are told by Chandler, Clarke, and the rest of the older travellers—has a peculiarity of its own, which we see reproduced, not alone among the prehistoric ruins of Sicily, but also in European work bearing certainly no older date than that of the seventh or sixth centuries. In the paintings, too, as in the bas-reliefs, vestiges of a kindred art are visible, as, for instance, when the human figure is introduced, the anatomy, the muscular display, the attitude, the eyes, the movement, so to speak. They all tell of an Assyrian origin, upon which another originality, very unlike the Assyrian, has been engrafted. So far with regard to the better class of relics, which the most modern of archaeologists are busily engaged, in both Cyprus and under the English protectorate in Asia Minor, in bringing to light. Naturally, they anticipate making no such rapid progress with their architectural researches. Even in this direction, however, the promises of

new discoveries, or enlargements on a grand scale of old discoveries, are already announced. They correspond with much that had already been established with respect to these monuments of archaic art, belonging, for the most part, to the ante-Grecian epoch, though, in a great degree, the native art of Asia Minor may be said to represent no style at all. It may be said to have been, from Lydia to Cappadocia, mere rude sculpture in the rock, largely made up of animal forms, rather Babylonish in its outward features, and suggestive of questions appertaining rather to ethnology than to art. The excavations now laying bare below the lines at which the monuments were formerly supposed to cease, the Nymphian bas-relief, near Smyrna, the Giaour-Khabri, in Phrygia, the Lion of Kalaba, and the gates of Mycenæ, all point, though from different periods, to the same history. There is thus a mingling of many ages among these treasures, which French explorers are ransacking, while English administrators are taking over the guardianship of the country above the surface. Among their latest discoveries may be enumerated some fragments of walls lined along the summit with plates of polished metal, resembling those identified in the now famous “Treasury of Atreus,” at Mycenæ, which plates were attached to the masonry by means of nails; bits of a frieze ornamented with bronze leaves, also nailed on to the foundation; the ruins of a timber roof, which, apparently, had been subjected to some powerful preservative process, and which, it would seem, had served as the covering for a house constructed altogether of wood; and slabs, evidently of pavements, painted with the figures—symbolically conceived—of lions as guardians. This was, to judge from the remains unearthed, a common ornament of doorways of both tombs and houses, and is to be found alike in front of the gate of the mausoleum assigned by tradition to Midas, and in that of a cottage door in nineteenth-century Cyprus. An even more interesting discovery, however—led up to, no doubt, by others—has been made, and this is the very common character of those “chimney” funeral chambers once supposed to be so rare. They are believed to be of Phrygian origin, but their remains are at present to be found, though not in very great abundance, all the region over, insular not less than continental. By the peasantry they are to this day called “stone-piercers,” or, literally, “holes in the wall;” but they were, strictly speaking, funnels excavated from below to above in the rock. A sham door was first carved on the front surface of the solid stone, above it was hollowed a niche, which, when occupied by a dead body, was closed with an upright slab; and so, upwards and upwards, until the summit was nearly reached. Little art was wasted upon these Orientally Gothic sepulchres, though they are not all invariably alike. The latest archaeologist in this field found, in fact, at Kambet no sham door, no pretence of a “chimney” carried up through the entire mass of the mountain; only a deep mortuary cave, embellished with brilliant colours, and characterised by certain adornments, reminding him slightly of the Mausoleum at Halicarnassus. It is often confessed, however, by the most intrepid of these archaeological inquirers, that it is difficult to distinguish between the various characters and purposes of the innumerable monuments that travellers of late have recommenced describing and cataloguing. Thus, the colossal image on Mount Sipylus, between Magnesia and Smyrna, is set down as Niobe, though it gives no other idea than that of a gigantic female figure, seated. M. Soiry, the latest explorer, thinks it represents “the Mother of the Gods,” whose

worship is known to have flourished in that neighbourhood, and in the parts round about. But, singularly enough, there exists the fragment of an almost undeniable Niobe, crouched in a crevice of the rock, whence a fountain of water has flowed from immemorial time. But it is by far too early for even the most enthusiastic of modern explorers to have corrected, in these respects, the opinions of those who went before them, and whose labours were so long interrupted by the impossibility of pursuing them amid incessant wars and rumours of war. Allowance has to be made, moreover, for the barbarism in the keeping of which these monuments and their incidental relics have so long remained. Thus, an edifice called by the Turks in Cyprus, "the fortress of the Infidels," was, in fact, a shrine constructed in the rock of indefinite antiquity and marvellous sculpture, dating from an epoch in which the Turks did not so much as possess a name. The arms advanced, the broken bow and arrows, the girdled tunics, the bare limbs, the sandaled feet, the tiara-crowned head, the serpent ornament, the one bearded and the other beardless, all belong to some heroic period of art, to an age invisible, but which the Ottomans, not being artists in the highest sense of the term, found no difficulty in ascribing to some unbelieving builder of modern fortifications. Not far from this, recent discovery has alighted upon that which is believed to have been the Palace of a Cappadocian dynasty, though the theory is altogether conjectural. Certain it is, however, that the edifice is composed of enormous blocks of stone up to a certain height, whence the walls were carried up in brickwork, not dissimilar to that employed in the most antique structures of Nineveh. The outlines, too, have been more or less distinctly traced, including a Hall of the Throne, with galleries, whereon faint signs of the painter's handicraft are still to be detected, and what, at any rate, is assumed to have been the peculiar abode of the women and children. That which appears to have been a throne, guarded by two lions, lies overturned in the dust. Many other investigations similar to these are in course of being undertaken, on the assumption that the archaeologists, of whatever nationality, will not be disturbed at their labours; and it is anticipated that numerous processes of discovery, interrupted during a hundred years past, will be resumed, with a rich reward to the present generation; but the most immediate curiosity attaches, perhaps, to the results of the antiquarian work which has been begun in Cyprus.

LAMBETH INDUSTRIAL PAUPER SCHOOLS.

WE have not been able to get a view of the unpromised drawings sent in for the proposed Norwood Industrial Pauper Schools, notwithstanding we have made two or three applications; and the Board are apparently acting on the policy of keeping the ratepayers and the competitors in the dark. At a special meeting of the Lambeth Guardians held last Monday, the selection of three designs was confirmed. We will here give our readers an idea of the three designs placed first by Mr. Currey. It will be remembered that the designs were referred to that gentleman for his professional opinion, and in accordance with his recommendations the plans marked "Light and Air" were unanimously adopted for execution, the authors being Messrs. Coe and Robinson. The report of the referee considered this design met the requirements the best, and was the lowest in cost. We understand the plans have been forwarded to the Local Government Board, and we may now lay before our readers the prominent features of the design. The authors

retain not only the school-rooms, which the instructions required to be preserved, but the north part of the front building facing Elder-road, which they say will effect a saving of £1,500. The general disposition of the schools is a rectangular arrangement upon the pavilion system, the girls' and boys' wings being symmetrically disposed on each side of the administrative block, with easy access to all parts of the establishment, two open areas on each side of the administrative block being formed. The children's day-rooms and dormitories have windows on both sides, and the wings are of two stories in height; the boys, girls, and infants are well separated and under control, and the communication is by covered corridors. We observe all day-rooms have convenient staircases at the ends, the lavatories and bath-rooms are centrally placed in each wing, and the dormitories are all on the first floor, with master's or mistress's bedrooms, and have their specially attached day-rooms. The boys' wing has a range of workshops in its rear, and the girls' the laundry, which is conveniently located near the infirmary. One of the most noticeable features in Messrs. Coe and Robinson's plan, and to which probably they largely owe their success, is that a separate entrance for goods and tradesmen is provided at the south-west corner of the boundary in Crown-hill, where also the probation wards and the porter's lodge are placed. Although there may be some objection to this arrangement it is obvious that it simplifies the economy of the establishment by avoiding unnecessary traffic through the principal buildings, and the probationers are kept distinct from the inmates of the school—at least till they are capable of being admitted. The infectious wards form a separate block behind the probation wards, and appear to be planned to the regulation requirements, while the infirmary is ingeniously contrived at the north-west angle, the wings and centre forming an obtuse-angled block fitting round the corner of site. Referring to the site the authors observe, "The site upon which it is proposed to be built offers many objections to a building of the ordinary type, the narrowness and slope of the slip of garden ground rendering the idea of a long building upon this ground facing the south quite untenable, whilst any building placed upon the wider ground south of the garden must either be a long building facing the east or in a quadrangular form, in which case the wards would be so near the boundary that an adjoining owner building upon his property could materially injure the efficiency of the infirmary." The plan shows the boys' ward on one side and the girls' on the other, the wards divided into one large ward for ordinary cases, a special ward and a convalescent ward—each wing having its own stairs and lift; 850 cubic feet are provided to each patient. In the centre are the surgery, nurses' rooms, operating room, kitchen, and other administrative offices. We find the infants are placed in the present building, and this part has been arranged for two classes of infants—those under five years and those from five to eight, each having their own day-room play-shed. Referring to the administrative block, the dining-hall forms the centre feature, accessible from the wings by corridors, and well placed as regards the kitchen and offices, which latter are to the north. The other apartments seem to conform pretty well with the regulations. We cannot go into details, but we see the authors propose to adopt the Banner system of ventilation to the drains—that the beds in dormitories are placed with their heads to the wall, and that double beds are provided. The estimated cost is £20,070.

The second premiated design—"Terra Cotta," by Messrs. F. H. Fowler and Ald-

winkle—presents a very different distribution of the boys' and girls' schools. Instead of enclosing areas forming a quadrangle with four enclosed courts, the school wings are reversed outwards, as it were, and the administrative block is quite isolated, except by corridor connections on each side with the wings. The existing boys' and girls' school is retained as a distinct block in the rear of the administration department for infants. We observe the entrance is in Elder-road, and this serves for all purposes. The wings are cleverly planned, and provide for that control and economy of administration which are so necessary in all buildings of this class. The authors have adopted the pavilion principle, and have apparently carried out that plan thoroughly in the separation of these buildings. Taking one wing—the boys'—on the south side, we observe that it forms a straight block, running east and west, with a one-story cross wing at the west end for workshops, and a similar wing at the east end as a school-room, &c. The main portion has a covered playground and day-room, 30ft. wide, with windows on both sides, staircases at the end and centre, connected with which is a lavatory and bath-room. Above the covered playground is a double dormitory, with projecting w.c.; over the centre are the head master's and nurses' rooms, in direct communication with the administration block by an open corridor; and over the general day-room is another double dormitory for four rows of beds, under the eye of the teacher. The centre rows of beds back to a dwarf platform, and are placed head to head. The authors, alluding to this arrangement, say it "admits of economy and convenience of supervision, and is preferable to long and narrow wards, or wards 18ft. to 20ft. wide, with three rows of beds." One good point we observe in this plan is, that the corridors are short, and another good feature is that the school-rooms are of one story, with open roof, and can be entered from the playground. There is a double class-room. With regard to the lavatories and baths, the authors say, "we propose one large lavatory upon the ground floor, in preference to several adjoining the respective dormitories. We have made this a subject of special inquiry with the superintendents of several large schools, and their strongly expressed opinion is that it is far preferable to have the lavatory work concentrated in one large apartment on the ground floor, as the children wash three times a day, and it would be very undesirable for them to be continually rushing up stairs." What we have above described applies also to the girls' wing on the north side. The dining-hall is placed in the centre of the administration building, and its axis aligns with the two connecting corridors of the wings, which, in fact, surround it on three sides. An open roof is provided, lighted by a lantern. Adjoining is the kitchen, and the offices are grouped at the back. The master's and matron's apartments, committee-room, &c., occupy the front portion, and above this is the chapel forming a central feature. The probationary wards are at the south-east corner of land, and we may mention the authors in one of their schemes have endeavoured to meet the Local Government Board in their circular respecting a separation of the children admitted the first week from those of the second. The authors place the infirmary in the position suggested—the south-west corner—and their plan provides for a classification of cases, for each sex into four—namely, ophthalmia, 12 boys and 14 girls; cutaneous, 9 boys and 12 girls; cutaneous with ophthalmia, 9 and 12; and ordinary sick, 12 and 14 respectively. On the whole, we have reason for believing Messrs. Fowler and Aldwinckle's plan closely follows the Local Government regulations in several

important particulars, especially as regards separation and economy of supervision of the schools. The blocks of buildings avoid the objection of the Government Board to right-angle buildings higher than one story, and the plan is, in our opinion, economical. The total cost is estimated at £33,700. It may be mentioned that Mr. Aldwinckle was associated with Mr. Parris as the architect of the workhouse buildings at Lambeth, while Mr. Fowler carried out the infirmary. We may add that the authors submitted three schemes—one based on the cottage system found to answer so well on the Continent, especially in Holland, and of which we should like to see a repetition here.

We have not been fortunate enough to examine the plans of the third premiated design by Mr. Edward Clarke, of Adam-street, Adelphi, but from the particulars kindly furnished us we understand the author has met the condition as to the retention of the old buildings by designing the "new girls' dormitories and day-rooms, as well as their dining-hall, in separate blocks," these being brought into communication by covered ways, which will take the same obliquity as the ground. The boys' school is similarly arranged, the whole being connected by a covered way. Referring to the entrances, the principal one will be under the notice of master or matron, the goods' entrance, under that of the porter, whose lodge is also close to entrance gates. Speaking of the administration blocks, the author says the entrance building on Elder-road is in so sound and substantial a condition that he has re-arranged it, and the basement stores, kitchen, &c., are retained. The buildings are planned on the pavilion principle; but the author observes, "no pavilion has any high buildings on both sides of it, each being kept a space of 25ft. apart, permitting full access of air and sunshine." The boys' school is kept in the old building, with some alterations in the partitions to give the 9 superficial feet required by the Local Government Board. New class-rooms are proposed at the end. The dormitory is above for 113 boys. The girls' school is similarly planned, and the infants' existing school is retained, though lengthened. One advantage claimed for this plan is that the wards and day-rooms are well placed as regards the sun, their axes being east and west, and no pavilion is shut in between high buildings. In the dormitories Mr. Clarke has remodelled some of the old ones, and provided new for 80 boys, 200 girls, and 50 infants. The regulation superficial area and cubic space have been allowed to each child—namely, 25ft. super. of floor, and 300 cubic feet of space. Fresh air is proposed to be admitted to the wards at several points by gratings in wall near floors, and at the upper parts of windows, and Howarth's Archimedean screw is to be introduced to facilitate extraction in connection with shafts in the wall, and boxes between girders. The style adopted is plain, and the cost is estimated at £25,100. The author has taken much trouble in preparing tables of areas and cubical contents of each apartment. It has not been our object here to compare the merits of the designs critically, but we hope to be able to publish all the three plans shortly.

THE GOLDSMITHS' PRIZE DESIGNS.

A LARGER and, on the whole, better display of competition designs than hitherto have been submitted to the Company of Goldsmiths for their annual prizes, and these are now to be seen at the South Kensington Museum. The court set apart for them is certainly more likely to draw the public and the student than the old and cold quarters in Tufton-street, though we are

sorry the Architectural Museum has not retained so desirable an accessory to its attractions. We cannot say that we are quite satisfied with the award of the judges in the competition this year, for it appears to us that the premiated designs, with the exception of one or two cases, are, in point of ability and artistic conception, much below others that have gone without reward. If we take the £50 prizes first, no one of any judgment in art design would have placed the "Tea and Coffee Service," by Mr. Morrisson, before Mr. J. Watkins' design for a casket under motto "Dice Box." The tea and coffee service might be attributed to a novice; it is a flashy, overwrought, and elaborate piece full of labour and some painstaking drawing, but certainly not a thoughtful or masterly design. The coffee and tea-pot do not at all accord in style, and there is a great lack of repose and simplicity. On the other hand, Mr. Watkins' design for a casket is a classical conception worked out with much taste, and the drawing is clever. The story of Meleager is pleasingly introduced in two square panels, one representing Althæa and the other Atalanta; the curvilinear top, pedimental in form, surmounted by a group, and the base with claw feet, both display merit of composition. The drawing is spirited, and executed in sepia; and, we may add, Mr. Watkins is no tyro in these contests, having taken prizes before, and only the year before last for a large shield. Another of the £50 prizes for plate is awarded to Mr. Alex. Creighton for a chimney-piece clock-case, under motto "Tempest." It is in silver and gilt, simple in outline, with domical top and an emblematic personation of Time, it has angle figures, and is mounted on a black marble moulded base, but we cannot award it much higher praise. For modelling the work this year is somewhat below the mark. Mr. Garbutt, a life student of the Architectural Museum, takes the £50 prize for a model of a shield, under motto "Olive Branch." It is convex, of circular shape, but the centre allegory is particularly wanting in unity. The relief figures of "Peace," "Spirit of Evil," and "Death" are badly grouped, and there is a singular want of aim and breadth in the composition generally. Equally displeasing to our mind are the great and uncouth masks introduced round the border, and the scrollwork, which are both out of scale and wanting in refinement. Far better specimens of modelling are two vases—one by Mr. Vigor, jun., a small vase with subjects in relief, elegant in outline and refined in the modelling of subjects—the cover is also chaste; and another model by Mr. Marshall, in the same case, albeit its outline is heavy, shows some admirably-composed groups in relief, executed with much spirit and feeling, and displaying the hand of a master, and we are surprised to find from the intelligent attendant that no prize has been awarded it. Passing to the case of plate, we may mention that one of the £25 prizes has been given to a goblet or tankard in repoussé work of exceedingly good outline, and the figure subjects surrounding the cup are bold and telling. In this case of objects in executed plate we notice some repoussé on steel and an excellently modelled bust, but the designs are generally indifferent, and some few of them indicate a poor conception of outline, and a total ignorance of the elements of plastic art. Another of the smaller prizes is awarded to a design for a silver salver by Mr. Tidmarsh. We have nothing to say in disparagement of the labour and careful drawing in Indian ink of this subject, but the design, to our mind, is destroyed by the overworked treatment of the relief subjects, illustrating Dryden's "Ode to Music." The centre feast is clever *per se*, but the effect with the border

medallions is anything but quiet, and the design, in our opinion, cannot compete in point of merit with another in the same screen under the motto of the "Three R's," which, for simplicity, breadth, and refined taste, is far its superior. The latter is in repoussé in oxidised silver, and the composition of figures and ornament in the rim and the centre leave little to be desired. The author, however, does not get a prize. Another prize is won by Mr. Rhead for a wine fountain or cooler. There is considerable merit in the drawing; the relief subjects are cleverly shaded in sepia, and the design of the figures good, but the upper part of vase is not pleasing, and is certainly ill-proportioned to the base. "Procrastination is the Thief of Time" is a well-designed "Treasure Box," of somewhat conventional form, and illustrating on its sides relief subjects of the "Toys of Childhood and Manhood" skilfully treated. We may also notice a clever drawing by Mr. Vigor of a Titan shield, oval in form, with a cleverly composed border, in which the warlike figures are skilfully handled. The centre figure and oval, however, suffer from extreme elongation and want of proportion. A design for a double mirror—"Venture"—is certainly original and clever. It is of ovoid form, surrounded by a frame of elegant treatment, from which pendent lights are hung, and the groups of figures on the base of the triangular stand and at the top, illustrative of features of Solomon's virtuous woman, and of "Simplicitas, Hilaritas, and Caritas," are exceedingly well grouped and appropriate. We think this design worthy of a prize. A design for a timepiece on the same screen is too naturalistic in treatment, but the four figures allegorical of Twilight and Night, Dawn and Gloom, are skilfully introduced at the ends and sides, Time surmounting the top of a simple lined composition. The drawing is cleverly executed, and in quite classical feeling. A few other works may be mentioned, such as a specimen of silver engraving for which a £25 prize is awarded. There is certainly a chasteness in the engraving that we admire. An inkstand under motto "Excelsior," with a good group of three figures, Renaissance in style; a tea service under the motto "Novelty," in which the artist has paid attention to the principles of form as applied to the treatment of vessels with handles, the ornament being simply incised on the surface; a rather cleverly-designed biscuit-box, with some well-designed figures in relief round it, under the motto "In Spe Laboro;" a spiritedly-drawn flagon, rather overdone, with crossed crayon and compasses as a motto; and a design for a reading lamp in silver gilt, with motto "Bagatelle," rather too low, but cleverly illustrated with medallion subjects round the base and stem. On the whole there is more merit to be found in the collection than there has been for the last few years, though we should be glad to find the student's work more taken out of the groove of the "silversmith's" style. In the execution and workmanship we especially mark the influence of trade patterns and types. Thus one of the engraved salvers is extremely naturalistic—so much so that the subject represented would have been better as an example of engraved work simply than intended to enrich a silver plate. In some of the repoussé work also the idea of metal relief has not been kept in view, and the modelling shown might be better adapted for wood or stone.

NEW BUILDINGS AT CHELSEA.

SOME time ago we drew a picture of modern Chelsea, as it has been partly rebuilt by the hands of some of the Queen Anne revivalists; and we called attention to some striking houses in Cheyne's-walk

and Queen's-road, facing the river—among them "Swan House," and several residences in the "Queen Anne" and Vernacular Gothic styles. We now draw attention to some new houses, built in a more pretentious manner, on the Cadogan estate—a site adjacent to Prince's Cricket-ground, and accessible from the Brompton-road or Sloane-street. It is hardly necessary to remark that, during the last and preceding centuries, Chelsea was a highly fashionable neighbourhood; and during the later Stuart era it held an important position in the art world. Its porcelain works were justly celebrated all over the world; and the tendency of its taste then was essentially towards that which prevailed in the Netherlands. The style of its buildings held undisputed sway; and the architects of our own day, with a sort of sentimental reverence, are now reproducing its older features.

Facing Cadogan-square a block of six red-brick houses, of mansion-like pretensions, has been erected, displaying among others the hand of Mr. Norman Shaw. The visitor to this part is struck by the variety of the gables, in which every conceivable form of Flemish quaintness has been attempted—albeit the diversity rather destroys the effect of accidental picturesqueness that has been aimed at. What with the right-lined and curvilinear—the studied irregularity of window spacing, and the conceits in the way of cut-brick "pedimentation" (if we may coin a word)—the eye is rather distracted, and we look in vain for that Old English or Low Dutch simplicity which we have been constrained to admire elsewhere. In this group of houses we at once perceive the dainty detail of Mr. Shaw in the centre house of the block. The house is of considerable frontage, five stories high, and is crowned by a straight-lined gable, finished by a small pediment, and broken on the face by pilaster-like projections, in rubbed brickwork, which divide the gable into two stories. Three close-set, large, and lofty-proportioned windows mark the chief story, and these have rubbed red-brick pediments, with rather heavily-carved keystones breaking through the mouldings. The sash-frames are, as usual, divided into small squares, painted white. On the right a projecting oriel of three stories of octagon shape, breaks forward and destroys the symmetrical division; and we regard this as the best bit in the whole elevation. Richly-carved panels, with brick carved festoons, form the finish at the top, below which is a bold and very effective cut-brick cornice. The lowest tier of windows is finished with small high-pitched pediments. The unfinished state of the lower part and interior does not permit of our saying anything at present with respect to them, though we have all the evidences of freshness and vivacity characteristic of the architect's work. In the adjoining houses, still unfinished, the style has been treated with less effect. The gables are overdone, and the pediments within pediments lack the more genuine vigour of the style. In execution, however, there is little to be desired (Messrs. T. Pink and Son are the builders). Mr. W. Young, in an adjoining block of four houses, is following—if we can judge from their present incomplete condition—a purer phase of the Renaissance; while Mr. J. J. Stevenson, at another end of the new square, has a large site, upon which are to be erected houses of the decidedly fashionable style. Overlooking Prince's Cricket-ground, in Pont-street, the last-named architect has been displaying all the resources of "Queen Anne" in a row of about twelve mansions, built in a very substantial manner by Mr. Thos. Pink. We must confess that, looking at them from a sharp perspective point of view, they scarcely come

up to our expectations; and we might have passed them over in a general survey of the locality. Their fronts are scrupulously executed in yellow, stock, and red brick, intermixed; but they rather jar on the eye, and produce something like what musicians call a "Dutch concert." In one or two instances ornamental red brick frontispieces are relieved upon white brick; but we prefer those entirely in the former material. Bay windows are largely introduced; and the porches display a singular diversity, and are open to the charge of being somewhat squat. In one case the brick porch is covered by a flat projection of the balcony, under which turned pillars are introduced, resting on the brick parapet of the porch; and we have the singular resemblance to a table resting upon it. Entering one of the more finished of these costly mansions, we find them very commodious. On the ground floor, the vestibule and hall are paved in mosaic; and we enter a morning room, having a bay window, with a chimney-piece of massive and effective design, partly marble, within a framing of rich oak mouldings. Above the mantelshelf there is a composition in oak, with mirrors, and richly-carved panels; the fireplace is splayed with tiles. Behind this room is a library, about 18ft. x 12ft., with a chimney-piece of similar design, though plainer, the floor, as in all the rooms, having a parquet border. Both these rooms have deep cornices and friezes; and in the front room we observed the frieze is enriched by painted subjects and folial scroll work. The cornice members are relieved in bright tints, and the walls are to be finished in grey or some neutral green. In the rear of the library is an area for light; and below the staircase a rather irregular area is converted into a lavatory and cloak-room. The dining-room forms the extreme end, its door opening from the back corridor facing the main hall. It is a fine room, about 30ft. x 20ft., with an end bay—the lower panes having painted glass, with emblematical devices. The walls, chimney-piece, and finishings are pleasing, though not so characteristically quaint as many others in the style. The hall and staircase are decidedly gloomy; and the great depth of the house seems to call for a lantern or top-light to this part, instead of the rather awkward and indirect means of lighting from the small court. The first floor has a front and back drawing-room, extending over the morning-room and library below—the dining-room being another large drawing-room, or *boudoir*; and these have been handsomely finished with carved oak chimney-pieces, relieved cornices, enriched friezes, and dados, with emblematic medallions and scrolls—the walls being painted in shades of colours of moderate tone, the warmer tints being reserved for those rooms having a north aspect. Mr. Chevalier, of Westbourne-grove, is the artist of the decorations. The upper floors contain twelve bedrooms, with conveniences; and the views from some of the rooms are very extensive. A serving-lift and a servants' staircase are provided; and stabling—including two stalls and loose box, coach-house, and coachman's rooms—is arranged in the rear. In many of the other houses a billiard-room is obtained at the back, on the ground floor. We may add that the rents of these houses range from £600 to £700 per annum, and the selling prices from £7,500 to £10,500. Two or three of the houses are already taken—one by Sir Charles Buchanan, and another by Lady Leveson Gower.

Two other blocks of red-brick mansions must be mentioned—one facing Pont-street, and the other abutting on Cadogan-square—Messrs. G. Trollope & Sons being the builders. One block consists of five, and the other of six houses. In plan the

arrangement of each house is compact. There is a dining-room, about 28ft. x 16ft., a library behind, and an area for lighting, with a billiard-room in the rear, on the ground floor; above, a fine front and back drawing-room, *en suite*, with a *boudoir* over the billiard-room. There are about eleven bedrooms and two dressing-rooms; and the houses are provided with back stairs and every convenience, though they are not sufficiently completed to enable us to form any idea of their internal fittings or decorations. Externally the architecture is of a more sedate kind than those we have been writing about; and the architect has introduced rather the more moderate features of the sombre brick architecture of the Early Georges than the half-Flemish peculiarities of Queen Anne. The centre house in Pont-street front is crowned by an ornamental cut gable, and, with the end houses, projects a little, allowing of a balcony being formed along the first floor of the intermediate houses on either side. This balcony is arched above with flat arches, supported on red Mansfield stone columns, forming an arcade. The stone corbelled balconies of the other houses are somewhat heavy and coarse in detail; but there is, on the whole, a breadth of treatment that is wanting in the other buildings we have described—which, when the block is completed, and the sashes are fixed and painted, will atone for the otherwise unredeeming effect of the red brick fronts. There is a pleasing harmony of contrast between the warm stone and the brick which avoids the patchy effect a lighter stone would have. Little carved brickwork is introduced, and this is only in the gables and the pediments, and carved figures in niches in the upper part of the piers to the ground story. The gable dormers and the chimney-stacks break the roof outline; and the blocks certainly contrast, in their mass and plainness, with other houses on the same estate. If we remember rightly, these red brick houses are from the design of Mr. J. T. Robinson, whose original drawing at the Academy, two years ago, we admired much, though the executed buildings, unfinished as they are, hardly bear out the sketch in colour.

Other large buildings have lately been erected on the Cadogan and Hans-place estates, but in a less characteristic style. In the Square we observe a few in a purer Renaissance garb; but the difficulty we find in all of them is the means for lighting the hall and centre rooms, owing to the necessity of providing more than two rooms in depth. The best mode of meeting this is to provide a central hall or staircase, which may be lighted at the top or at the side, from an area common to two houses, forming a balcony or gallery approach to the rooms in the rear. In Sloane-square a large block of new buildings is nearly completed in stock and red brick and stone, but having few pretensions to notice. We cannot leave the locality without referring to a church for the Roman Catholic communion approaching completion, from the design of Mr. Bentley. It is designed in an extremely severe style in white stock, with stone dressings, and is close to the new Cadogan-square, and on a prominent corner site. Both in outline and detail it displays the work of a master in Gothic; and we have seen few churches more thorough, or in a truer mediæval spirit. It has a nave, two aisles, and a transept—the last being kept flush with the aisle. The most pleasing view is the north-east, with a gable end of extreme simplicity, flanked by an octagon turret at the angle, finished below the gable. The end is pierced by four very narrow lancets, under an enclosing arch—the outer lancets being separated by narrow stone buttresses, springing out of a set-off below. The effect of this with the buttress and

turret is exceedingly dignified. Within this window is a drop-traceried arch, forming a passage between, having a very rich effect. The west end has also a four-light window, separated by buttresses. The clerestory is lofty, pierced by a number of narrow lancets, in recessed square heads, slightly cupped. The end of the north aisle forms a chapel, and has a Decorated tracery window; but this is the only ornate external feature in the whole building. A low conical tile-capped turret rises at the west end (between nave and aisle), and—with the unpretending lines of the nave, aisle, and transept, and the red-tile roofing—produce a very satisfactory ensemble. Messrs. Braid & Co., of Chelsea, are the builders.

M. EUGÈNE VÉRON ON ÆSTHETICS.

THE French have long enjoyed a certain supremacy in art. In all that pertains to the artistic instinct, in a keen appreciation of the beautiful and refined, in a nervous sense of artistic combinations in form and colour, the French are undoubtedly our superiors. If we are disposed to deny them the vigour, and sometimes originality, which characterise our own works, we cannot doubt their art has been less the victim of change and coarseness than ours. But the fact is more forcibly impressed upon us when we read their treatises on art and æsthetics and compare them with English books. We have seldom read a work of greater merit than that lately written by Eugène Véron, entitled "L'Esthétique," and which has just been freely, and we may add ably, translated by Mr. W. H. Armstrong, B.A., for Messrs. Chapman and Hall's "Library of Contemporary Science." We shall only dip into the book and endeavour to give the gist of his theory. M. Véron's treatise, we may say at once, attacks many of our conventional and long-treasured ideas about art. He disabuses the reader's mind of much cant and tall talk; he clears away much metaphysical dreaming, takes the subject out of the ideal mist with which it has been obscured, and tells us plainly that "art is nothing but a natural result of man's organisation." Those who have been dreaming of the transcendental origin of art and the artistic genius will perhaps be displeased by this definition, but the sooner they begin to recognise the fact that particular pleasure may be derived from certain combinations of forms, lines, and colours, the more hope is there of art becoming general and more intelligently understood. No one doubts now that music itself can be resolved into a law of harmonic succession of vibrations, and M. Véron maintains what has been asserted by a few others among us, that "the principles of the two groups of art find their explanation in the two sciences pertaining to the organs of sight and hearing—namely, optics and acoustics." Having brought the domain of art within that of science, he deduces another important principle, which we give in the words of Mr. Armstrong, his translator—namely, "that outside the material conditions that relate to optics and acoustics, that which dominates in a work of art, and gives it its special character, is the personality of its author." He goes on to say "the value of the work of art rests entirely upon the degree of energy with which it manifests the intellectual character and æsthetic impressions of its author." Here we have a statement which the artist who claims the most ideal origin for his art will not dispute. Then, again, some comfort will be gathered from the further qualification of the author, who adds in effect that the only rule imposed upon this personality is the mode of thinking and feeling of the public to which the work appeals. We further quote: "A poem may express senti-

ments or ideas, which, although they are incomprehensible to the contemporaries of the author, are not on that account the less worthy of the admiration of a more enlightened period or country. Such a want of harmony, as a matter of fact, often causes a work to fall rapidly into oblivion." But we pass on to remark that M. Véron treats all formulas that have imprisoned art—as "idealism," "naturalism," "realism"—as different points of view in regarding art which is not contained in any one of them. Each may recommend itself to certain individuals or national temperaments, but it is absurd to force them upon all. Thus, as he justly says, "it is ridiculous to condemn Flemish or Dutch art in the name of Greek"—a doctrine that ought to have its weight with those architects who stick to one style and ignore all others. One fact is also made clear—and that is, art is gradually withdrawing itself from mythology and metaphysics, though we cannot fully concur with the author in thinking that it is detaching itself entirely from symbolism in the direction of humanity—not so, at least, in one obvious direction. The tyranny of academic routine and official teaching is energetically exposed by M. Véron, and in this argument he supports and quotes largely from Viollet-le-Duc in the doctrine that great art writer has maintained with so much unflinching consistency, that without independence we can have neither art nor artists. Let those who have all along allied art, and especially architecture, with despotism, read M. Véron, "All the great art epochs have been epochs of liberty" (*Toutes les grandes époques artistiques ont été des époques de liberté*). "In the time of Pericles as in that of Leo X., in the France of the 13th century as in the Holland of the 17th, artists were able to work after their own fancies." No art dictatorship or official corporation interfered. The author might very well have added English art to this catalogue, less controlled as it is by academic training than in his own country. The Académie des Beaux-Arts, of course, comes in for a share of well-merited invective. It is said to be the most powerful enemy of progress. Dead forms of architecture are reproduced, and everywhere education is founded upon the imitation of the past. We need not follow any further the author in this opinion, shared as it must be by every well-wisher of architecture and art, and by every thinker in both France and England. Of the three forms of art—conventional, realistic, and personal—the latter only is considered as deserving the name. The first is pronounced the negation of art, the second is impossible, for the artist cannot "disappear entirely behind reality," while the "source of all poetry is the soul of the poet." Though we commend the principle of personality in art, we cannot go so far as to say that the Renaissance was an incoherent and impotent manifestation of art; the author himself in speaking of architecture, admits that it is the least personal of all the arts.

It would be impossible, in a brief notice, to give the views of the author upon the origin and grouping of the arts, the source of æsthetic pleasure, the definitions of taste and art, though of these we may mention M. Véron has accepted the physiological explanation of our sensations of pleasure as laid down by Herbert Spencer, Mr. Grant Allen, Professor Bain, and others. He also maintains that the principal forms of art "grew by a process of continuous duplication from written and spoken language." "Architecture," he says, "if not derived from written language, goes back to a common origin with it, linear composition and design being common to both." Under the organs of sight the following classification is given:—

Written language	} Sculpture, Painting, Architecture.
Order	
Proportion	
Simultaneousness	

We will confine ourselves in the present notice to M. Véron's views upon architecture in Part II., and here we can only glance at the conclusions. He first exposes the fantastic theories of M. Charles Blanc, who upholds the symbolic school, in "La Grammaire des Arts du Dessin," and of Lamennais, who holds a pantheistic theory of architecture; and in support of his views quotes from V. le Duc. Architecture is shown to have sprung from the natural aggrandisement of man's primitive dwellings. After convenience and use were satisfied, architecture strove to convey an idea and to excite admiration, and such admiration was the cause of artistic conceptions. After all then, according to the author, there is not such a mystery in the origin of architecture as some imagine. Style is the result of "methodical observance of a principle," according to Viollet-le-Duc, and is developed in works of art in exact "proportion as they spring from a just, truthful, and clear impression." The author's sympathies are undoubtedly on the side of Gothicism, and he is an ardent supporter of V. le Duc. We have only room left to give the conclusions of the author:—"Architecture is first an industry, and then an art. Whether its task be to construct a temple, a palace, or a theatre, it must in the first place accommodate its work to the predestined purpose. Nor is this all—due consideration must be given to the requirements of materials, climate, light, situation, and habits, which are all matters demanding great skill, tact, and forethought, but can hardly be considered as belonging to art in its strictest sense. They do not give the architect much opportunity for the exercise of his æsthetic powers. In the majority of cases," he goes on to say, "the forms of monuments were more or less borrowed from those of ordinary buildings, and were therefore determined by the ensemble of qualities and conditions which constituted the collective genius of the race, causing the individual and personal predilections of the artist to be under considerable restraint. Referring to expression, the author observes the power architecture has of giving it. It can be the calm or bold, graceful or powerful, solemn or gay, as the architect has the ability to observe the impressions of certain lines and their combinations. For instance, horizontal lines create ideas of stability and weight; vertical lines of boldness and aspiration; plain surfaces, if they predominate, suggest austerity and gloom; while many openings produce opposite ideas. M. Véron directs some trenchant remarks to architects in the following passage: "Great architects are those who are able to tell in advance, with accurate knowledge and feeling, the exact effect which all these various conditions will have in the finished building;" and this ability, he goes on to say, can only be acquired by a series of experiments in which each part is reduced to its just importance. Architecture remains, even from an æsthetic point of view, so dependent upon geometry, upon mechanics, and upon logic, that it is difficult to discover accurately the share which sentiment and imagination have in it. No architect can gainsay these remarks. How few of them, we wonder, really ponder and reflect upon the real forces they have at command, if they can only wield them aright? The illogical use of forms divorced from their original purpose, in order to act as ornaments, is reprobated with much force, and is likened to the tall phrases of the fine talkers of Molière and La Bruyère, who were never content to talk of things as they are. "We could wish," says our author, "that our architects would follow the ex-

ample of their predecessors instead of allowing themselves to be dragged through all sorts of queer ways by a deplorable spirit of eclecticism." It will be seen that M. Véron strikes at the root of many false notions and artistic prejudices; he clears away much that is mystical and confused in aesthetics, and defines it simply as the science of beauty in art. Art, we learn, is essentially subjective, and the artistic genius consists mainly in a faculty of seeing things in their *ensemble*—the artist, in fact, epitomises form; from the moment an idea seizes him, he exists for it alone, his creative power is essentially synthetic. The critic, on the other hand, has nothing in common with the artist, except love of art; they are opposite poles of humanity (their intellectual constitutions are different), while the work of the former is analytic, requiring the predominance of the reason. Finally, the author shows the irreconcilable processes of creation and criticism; he denounces the official art-teaching of France as a veritable bed of Procrustes, and affirms that all art worthy of the name is human and personal to a certain measure. It is still the individuality of the artist that produces art, the difference being that this personality formerly occupied in the search after the superhuman is now contented with love of truth and life. We thoroughly agree in the final remark, that if this be called a debasement of art we might as well say that Science debased herself when she substituted Why for Because, experiment for ontology, and when she added the study of the earth to that of the heavens. Into the subjects of sculpture, painting, music, and poetry, we have not entered, leaving to the reader these interesting sections of M. Véron's work.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE ordinary meetings of the Institute were resumed on Monday evening; the President, Mr. Charles Barry, F.S.A., in the chair. The Secretary read letters of condolence, written in the name of the Institute, to the Queen and to the widow of the late Mr. Frederick Pepys Cockerell, hon. secretary. The President mentioned that he had received a letter from Mr. Horace Jones, who was now in Venice and nearly restored in health, although it was to be feared their friend would be unable to return this session in time to read his promised paper on "Electric Lighting." Mr. Jones had presented to the Institute his designs for a bascule eastern bridge over the Thames, and also a medal of Temple Bar made from lead from the ruins. Amongst the members who attended for the first time since election were Mr. Calderon Marshall, R.A. (hon. associate); Mr. H. L. Florence, P.A.A. (fellow); and Mr. Charles Barry, jun., the President's son, and Mr. Herbert A. K. Gribble, introduced by the Secretary as "winner of the Brompton Oratory Competition" (associates). The following were elected to membership:—As fellows: Messrs. John Bryce, Edinburgh; Percival Gordon Smith (architect to the Local Government Board), Highfield, Stonebridge-park, Willesden; Thomas Edward Colcutt, 36, Bloomsbury-square, W.C.; and Thomas William Cutler, 5, Queen-square, Bloomsbury, W.C. As associates: Messrs. Septimus Cecil Searle, 66, Ludgate-hill, E.C.; Lewis Edward Hickmott, Rotherham, Yorkshire; John Frederic Shenton, Rotherham, Yorkshire; Adam Francis Watson, Lampport, Northamptonshire; William Daniel Bayliss, Singapore, Straits Settlements; Frederick Pinches, 359, Strand, W.C.; Charles Augustus Gould, 20, Great George-street, Westminster, S.W.; William Woodward, 13, Granville-square, W.C.; William Grollier, 17, Abchurch-lane, E.C. As honorary associate: Mr. John Everett Millais, R.A., 2, Palace-gate, W.

REMAINS OF BUILDINGS IN MIDIAN.

The PRESIDENT invited discussion on Captain Burton's paper, read at last meeting (page 637,

Vol. XXXV.), expressing a fear that no member had visited the land of Midian, and hence there would be no opportunity of contradicting the statements made. Captain Burton had begun by apologising for reading such a paper in that room, but although he had spoken of very few architectural remains, and only in a single instance had described a detail, yet he had found extensive traces of buildings, which led to conjectures as to their use and character. Apart from architecture the subject was an interesting one, and no apology was needed.

Professor KERR inquired whether Captain Burton had seen any architectural proof that any of the remains were anterior in date to the Roman epoch.

Captain BURTON said the buildings were constructed of a crumbling alabaster, and might be of any age. Amongst the coins he had found was a forgery of a Greek coin of 300 B.C., made of a plate of copper with thin coat of silver. With it were barbarously executed local coins of genuine metal. He only knew of one dolmen in Midian, described to him as a flat stone, supported on three others, but this he did not see. He found some stone circles, which were common all over Arabia. He indicated on the map the places which he thought would best repay mining—one near El-Muwaylah, for copper and silver, and one at El-Marwah for gold. The Egyptian mines were almost worked out to the last fibre, but in many places in Midian the workings were not more than 40ft. deep, for the miners were not able to cope with water.

THE MODERN RESTAURANT.

A paper bearing this title, by Mr. THOMAS VERITY, was read for him by the Secretary. Having remarked upon the insufficiency, dirt, and discomfort of the accommodation provided till very recently in London for those who sought their dinners elsewhere than in their own houses, the author said that recently some well and handsomely-appointed saloons had been opened for supplying refreshments—a change for which the public were in no small measure indebted to the proprietors of the Criterion. The site upon which it stands was formerly occupied by two hotels, both celebrated in their time—the White Bear and Webb's; the former was one of the old-fashioned galleried inns. As, after a trial of seven years, said Mr. Verity, the proprietors can suggest no material alterations, the Criterion may be considered to fairly meet the requirements of business. By the aid of a series of diagrams, plans, and sections, the building was described in detail. (We illustrated the Piccadilly façade and ground and grand-hall floor plans March 21, 1873, Vol. XXIV., p. 330, and further described the building on the occasion of the Institute conference visit, June 26, 1874, Vol. XXVI., p. 709). The public portion includes dining-rooms of various capacity, restaurant, grill-room, buffet, smoking-room, a grand hall (now used as a *table-d'hôte*, but originally intended for a ball-room), lavatories, retiring and cloak rooms, and a theatre. The service departments are arranged in a central block one over the other, corresponding in level with the different dining-rooms, and in communication with one another by means of lifts and staircases. They comprise kitchens, sculleries, larders, pantries, cleaning-rooms, wine, beer, and ice cellars, and store-rooms for plate, glass, linen, groceries, and all kinds of provisions. The general arrangements are: on the ground floor—the principal entrance, in the centre of the Piccadilly façade, under a recessed archway, opening into a vestibule, 30ft. by 25ft., forming the central means of communication with all the public rooms. On the right of the vestibule is the restaurant, 70ft. by 30ft., and on the left the buffet, 90ft. by 25ft., with smoking-room, 40ft. by 25ft., at the further end. There is also a side entrance to the buffet from Piccadilly, having on the right a small bar, and on the left a cigar shop, and another entrance to the buffet from Jermyn-street by the secondary staircase. Advantage has been taken of the difference of level in the streets to obtain in a half-basement a second-class dining or grill-room, while to gain greater height the floor of the smoking-room has been raised 2ft. above the general level. On the first floor on either

side of the vestibule are rooms, each 50ft. by 25ft., for banquets, &c., and ranged along the corridor are private rooms of different sizes for parties from ten to fifty persons. On the second floor is a large room approached by either staircase, used principally for Masonic purposes. On this floor, but at a somewhat higher level, is the grand hall, 80ft. by 50ft., and 35ft. high; this room occupies the whole length of the Piccadilly front, and is lighted by the range of great windows looking towards the street, and by a large glazed dome in the centre. The kitchens and servery are arranged on six successive stories in a vertical series in direct communication by means of lifts and the servants' staircase. The dormitories for the barmaids and managers are arranged round the dome in the roof over the grand hall in two stories, and accommodate twenty-four persons. The stores' entrance is in Jermyn-street, everything being conveyed by a lift in the area to the lowest basement, where the receiving clerk checks them, and passes them to their proper receptacles, from whence they are issued as required. Up to the present time the wine and beer cellars have been temporarily housed in the adjoining premises in Piccadilly, which are now being rebuilt and added to the Criterion. The idea of an underground theatre was suggested by the *Athénée* in Paris, but whereas that is only partially sunk, this is entirely below the ground floor. It was not originally intended for this purpose, but as a small concert-room, and was, indeed, constructed as a square galleried-room, and it was not until the entire carcass was built that it was determined to convert it into a theatre. Its position has been somewhat severely criticised, and all kinds of prophecies were made concerning it, some even going so far as to say that the audience would be stifled; but from careful observations of the temperature of most of the London theatres, this has been found to compare very favourably with the best. The entrance to the stalls and boxes is on the right of the central archway in Piccadilly, and for the pit and gallery from Jermyn-street, the corridors and staircases throughout being entirely fireproof. After much controversy with the Metropolitan Board of Works it was agreed that the floor formed a sufficiently fireproof party division to enable the theatre and restaurant to be considered "separate buildings." The entrances were ultimately modified, so that there was no connection between the two, except through the outer lobbies. The theatre occupies the length of the Piccadilly front, 80ft. by 50ft., and the height from stalls to ceiling is 27ft. It will accommodate over 1,000 persons. The stage is 25ft. deep with a proscenium opening of 22ft. Dressing-rooms are provided on both sides and under the stage, the entrance for professionals being by a separate staircase in the Jermyn-street area. Cloak and retiring-rooms are provided for all classes on both sides of the house. Only very limited storage is provided for properties, &c., the stores and carpenters' shop being elsewhere. The theatre, buffet, restaurant, and grand hall, are lighted at night by sunlights, having flues formed in the floors by placing rolled iron joists about 2ft. apart with slate bottoms and covers to contain the iron pipes, of which each light has three. The stage having such a limited height, the appliances are of a very special character, particularly as regards lighting. Wing burners are almost entirely dispensed with, the batton lights being mainly depended upon to light the scene. These have iron hoods with flue pipes, coated thickly with Leroy's cement, leading to the extracting shafts at the top of the building. The only naked lights on the stage are the float in front. For ventilating the apparatus has been divided into two divisions, one being the theatre, the large hall, restaurant, &c., and the other for the buffet, smoking-room, grill-room, and the dining-rooms facing Jermyn-street. For the ventilation of the theatre a fan is provided, 4ft. 6in. diameter, worked by a direct-acting steam-engine. It draws its supply down a series of air-shafts, formed in the main eastern wall, and forces it into an air-chamber formed under the theatre floor. From this chamber shafts are carried up in the walls to diffuse the fresh air at different levels around the whole

space. In addition to these branch distributing channels are provided for a supply of air for stalls and pit. Hot-water pipes arranged in coils are fixed in the chambers, in order that when found necessary the air may be warmed before its distribution. A water spray is also fixed in the main cold air supply for cleansing. For the extraction of vitiated air from the theatre, a centre perforation, 5ft., is provided, in direct communication with a powerful extraction shaft, 4ft. by 3ft., running up the entire height of the building. The waste heat from the grill store, and the products of combustion from sun-burner that lights the theatre, are carried up the centre of this shaft, in independent wrought-iron pipes. At the gallery level, and also at the back of the stage, four other retraction shafts are provided. When this apparatus is in full working the air supplied and extracted is equal to the entire renewal of the cubic contents of the theatre from five to six times per hour. The ventilation arrangements for the large hall consist of a series of inlets of fresh air around three sides of the hall, in direct communication with the chamber already described. The vitiated air is removed through the sun-burner, the perforations round it communicating with a main extractor formed over the dome. This plan of ventilation is generally applied to all the rooms. The hot-water services are worked by a steam heater fixed in basement, from which a 2in. continuous flow is carried through the departments, terminating in two spacious circulating cisterns, and a return pipe is taken back to the heater, passing all the lavatories. The questions of water supply and lifting machinery were considered by Messrs. Eastons and Anderson, who drew out a scheme, carried out by Messrs. Turner and Co., of East-street. A 5in. pipe is connected to the water main in Piccadilly, which, immediately on entering the building, branches into two pipes, each with a meter attached. One of these pipes supplies at high and the other at low pressure. On the roof a cast-iron tank is fixed, about 20ft. by 30ft., and about 4ft. deep, and from it are taken the supplies to the kitchens and other parts as well as to the lift. In the basement a brick tank is made, lined with asphalt, and to it is connected the service from the low-pressure pipe, and also the overflow from the other tank. The water discharged by the lift on its descent is conducted to the brick tank, near which is fixed a steam-pump, which draws the water from the brick tank and forces it up to the cast-iron one on roof. Thus no waste of water occurs, and the cost of the power for working the lift is represented by the steam used for driving the pump. The boilers provided for the heating and ventilating and the cooking apparatus also supply the steam required by the pump. On the high-pressure main and on the supply-pipe to lift are fixed on each floor fire-cocks with hose and connections; and since the upper tank has some 10,000 gallons of water in it a large supply is available in case of fire. The hydraulic lift consists of a wrought turned ram, 7½in. diameter, working water-tight through a gland at the top of a cylinder sunk into the ground, and has an oak cage on the top of it, with the necessary guides, valves, balance weight, &c. The length of the ram exceeds by about 3ft. the total height of the ascent cage (72ft.), being the height of the top kitchen floor above the lowest basement. The well for the lift cylinder is sunk to a depth below the basement of 80ft., or 110ft. below Piccadilly; it is lined with 9in. brickwork in cement, and finished 3ft. diameter in the clear. The London clay was not passed through until the extreme bottom of the well was reached, when a little water made its appearance. After the completion of the well it gradually rose until it attained a height of about 60ft. from the bottom. All the food lifts are worked by hand by means of an endless rope. The basement is considerably below the main sewer in Piccadilly, and it was thought that all the sewage would have to be pumped up, but fortunately it was found that in Regent-street there existed an old sewer 40ft. below the roadway. Permission to enter this was given, and a barrel drain was driven up Jermyn-street, into which all the sewage passes. Although provision had been made for arresting and collecting fat and refuse

by means of traps, yet it was found that a large portion passed into the down pipes, where it quickly got chilled and adhered to the surfaces, causing partial stoppages; this was at last remedied by turning the waste steam into them, which has the effect of keeping them warm, and so preventing any deposit. The first efforts were a mistake, as the steam was turned into the cast-iron floor gutters, and, owing to expansion and contraction, the joints soon became leaky. As to the general construction the whole of ground was excavated 30ft. below the level of Piccadilly, and the adjoining buildings underpinned. To keep the water back, the system was adopted of first building the back portion of the underpinning 14in. thick and rendering it with asphalt, leaving bond for the face work, the bonders being coated with and set in asphalt, as the outer work came up. The result is perfectly satisfactory. The concrete for foundations and the mortar is General Scott's selenitic; the floors throughout are fireproof, the basement and ground floor on Fox and Barrett's principle, and the upper floors on Dennett's system. All the main stanchions are protected by brickwork, and the girders either by concrete or plaster. During the building various modifications were made from time to time, which, in some cases, caused an entire change of the system of girders; the most notable being that caused by the conversion of the theatre. The Piccadilly roof consists of four Warren girders, 17ft. deep, the roof shape being made by saddle frames fixed to the backs, the whole very light and giving plenty of space for the dormitories. The whole of the Jermyn-street roof space being required, there could be no principals. It is, therefore, formed with an upper and lower curb as tension and compression girders, the whole of the strains being discharged at the angles. The distinguishing feature of the decorations is the tile work. It is here used very extensively as wall decoration, and it has the advantages of being bright and clean, practically indestructible, and not too expensive, and what is most important it will wash. The cartoons for the figure subjects were drawn by Mr. A. S. Coke, and the work was executed by Messrs. Simpson and Son, who also carried out the painted decorations in the various rooms and in the theatre. The room floors are laid out with parquetry by various makers. The vestibule is paved with marble mosaic by Barke. The building now in course of erection on the east side of the Criterion will contain on the ground floor a buffet and smoking-room, 29ft. by 70ft., with a still room at the end, to supply both the bar in the present building and also the additional one. The first floor is designed to be used either as separate dining rooms or a suite of Masonic rooms. The upper floor will be in communication with the grand hall, by means of a large opening which may be closed at pleasure by shutters, so that it may be used either as an extension for the *table d'hôte* or for private banquets. The service of all these rooms will be from the present kitchens. In concluding his paper, Mr. Verity referred to the Gaiety, which he has just reconstructed. There the business consists entirely of public dining. There are no private rooms. On the basement is a large grill-room, 90ft. by 33ft., with a double grill at one end and a dispense bar at the other. The grill is shut off from the room by a glazed screen, by which means, while all the operations of cooking the chops and steaks can be seen, the heat and smell are avoided. The room is very low, and mainly depends for light upon gas. The burners are enclosed in ceiling lanterns, having ventilating tubes constructed in the floor and entirely enclosed in the Dennett arching, so that there is no heat from this source. The buffet on the ground floor is 91ft. 6in. by 30ft., on the same principle as the Criterion, with a bar along one side, and lounges with tables on the other. On the first floor is the *table d'hôte*, the same size as the bar below, but the old floors above having been retained it is of somewhat limited height. The whole of the cooking is done on the top floor, and the means of communication is by lifts, of which there are three varieties. In re-constructing this building it became necessary to take out the whole of the Strand front and a part of the side front, as the former mezzanine was removed to give greater height

to the buffet. This involved a work of underpinning, probably the most extensive yet accomplished. This was done most skilfully, and with the most satisfactory result, by the contractors, Messrs. Geo. Smith and Co.

The President in proposing a vote of thanks to Mr. Verity, mentioned that in one of the maps of old London, in Mr. Craco's collection at South Kensington, there is in the fields on the site of the Criterion a little building marked "Gambling House." *Absit omen!* He suggested it would be desirable that, prior to the discussion, the members should have an opportunity of examining this building in detail, to which Mr. Verity replied that he would see Messrs. Spiers and Pond, and endeavour to arrange a meeting for Monday next, at 11 a.m.

STREET LIGHTING.

DURING the past seven days some remarkable experiments have been made by the Phoenix Gas Company, and other gas companies have intimated their intention to follow the lead. From the London and South-Western Railway Station to the foot of Waterloo-bridge is a broad road about 500 yards in length, till now dimly illuminated by the regulation sized gas-lamps, which are but little assisted by the light from the shops. The Phoenix Gas Company have boldly undertaken at their own expense to show what can be done with gas liberally though not extravagantly expended, and the result is satisfactory. The ordinary lamps have been fitted with burners, giving a light equal to 50 candles; while at crossings and corners burners ranging in power from 130 to 200 candles have been erected. The cost of the illumination has, of course, been materially increased, but the increase of light exceeds the proportionate cost of the gas, and Mr. Woodall, the engineer to the Phoenix Company, has demonstrated the fact that if the public desire a better light they can have it by paying for it. The number of lamps and the site selected facilitate comparison with the Jablochkoff candles on the Viaduct, and taking Mr. Woodall's figures we find that the brilliant gas illumination in Waterloo-road, if reduced at midnight, costs 1s. 2d. per hour, and as each lamp on the Viaduct costs 5d. an hour for the Jablochkoff candle only, the illumination supplied by gas is far cheaper than that of the electric system the Metropolitan Board of Works and the Commissioners of Sewers have chosen to experiment with. Similar experiments are about to be made by the Chartered Gas Company in the neighbourhood of the Athenæum Club—a burner of 200 candle power being placed a little south of the Guards' Memorial, two lamps of 120 candles each at Regent-circus, while the 38 intervening lamps will have an illuminating power of 80 candles each. In front of St. Stephen's Club one of Mr. Higham's lighthouse burners is to be erected, and in other places of public resort efforts will be made to meet the electric light by an increased and more economical use of gas. It remains to be seen whether the electricians can beat the gas engineers. The experiment in the Waterloo-road contrasts very favourably with that on the Embankment.

The village of Duffield, in the area of the rural sanitary authority of Belper, is about to be formed into a special drainage district. A system of sewers will be laid down, and the sewage disposed of by irrigation on an outfall site to be hired on lease from Lord Scarsdale. Mr. Thompson is the engineer for the scheme.

A three-light window in St. Mary's Church, Stafford, has been filled with stained glass by Messrs. Mayer and Co., of Munich and London. The subjects are six in number, and are taken from the life of Our Lord.

The Cardiff Town Council occupied on Monday for the first time the new council chamber—a portion of the town hall extensions carried out from the designs of Messrs. James and Seward by the executors of the late Mr. Jacob Bateb. In the course of the meeting a private bill was approved for the carrying out various improvements, including the purchase of the water-works, the enlargement of borrowing powers, and the making and enforcing of new by-laws and regulations. Mr. Peter Price was instructed to proceed with plans and estimates for a free library, to be erected on a site in Working and Trinity-streets, at an estimated cost of £13,000, the amount of commission to be 2½ per cent.

CHURCH OF ST. MICHAEL AND ALL ANGELS AT BEDFORD-PARK—NEW CLOTHING MANUFACTORY AT LEEDS—HOUSE AT SURBITON—SKETCHES OF PANELS WITH FOLIAGE—PRIZE DESIGN FOR A DAIRY HOMESTEAD.

OUR LITHOGRAPHIC ILLUSTRATIONS.

NEW CLOTHING MANUFACTORY AND WAREHOUSE, LEEDS.

The site on which this building stands is situate on the south side of Park-square, and was formerly occupied by a terrace of nine good houses, which had to be taken down. The building is in the Moorish style of architecture, and was designed by Mr. Thomas Ambler, architect, Leeds. It is built of selected hand-made pressed bricks, and red and buff terra cotta is used for the dressings. The four sides of the building are treated uniformly with the front, the north-west angle turret being used as a chimney to carry off the vitiated atmosphere from the gas engines as well as from the heating apparatus. The basement floor is used as a cutting-room, in which are a number of cutting-machines with endless knives, driven by power, the cloth being folded in layers, sometimes to the extent of one hundred and forty or fifty. The pattern of the garment is marked on the top, and the whole are thus passed quickly through the machine. There are three of Crossley's patent silent gas-engines, each of 8 h.p. One engine consumes about 8,000 cubic feet of gas per week. Two of them drive all the cutting machines, the hoist, and all the sewing-machines; the other is held as a reserve. White glazed bricks are used on the basement and third floors. On the ground floor are counting-house, two private offices, with lavatory and w.c.'s, packing-room, receiving-room, and warehouse-room for cloth. The first floor has no subdivisions, and is used entirely as a stock-room for made-up garments. The second floor is subdivided so as to provide in one-half of it a large dining-room, cloak-room, dressing-room, with lavatories and w.c.'s for the use of the females employed on the premises. The other half is used as a work-room. The third floor is used as a sewing-machine-room, with accommodation for upwards of 200 sewing machines, which are worked on an entirely new system, the patent of Mr. John Barran, jun. The roof is divided into four spans, the north side of each being glazed with rough plate-glass. The floors are formed with rolled-iron transverse beams, supporting 11in. x 4in., dressed longitudinal joists, 3ft. centres, and the whole covered with 3in. planks with iron tongues, dressed on the under side, stained, and varnished. The office walls are lined with pitch-pine framing, and the ceilings have moulded ribs and panels filled in with narrow V-jointed boards. All the joiner's work is of pitch pine, stained and varnished. The building is heated by hot water. The terra-cotta work was supplied by Messrs. Doulton and Co., of London. In the workpeople's staircase (which is fireproof) is carried up a 6in. water main, and on each landing is provided a double hydrant with valves and hose pipes. The following were the contractors—viz., brickwork, Messrs. Bentley and Burn; joiner and carpenter, Mr. John Tomlinson; plastering, Mr. John Senior; painting, Messrs. Wood and Son; slating, Messrs. Watson, Wormald, and Co.; plumbing, Mr. F. Johnson, all of Leeds.

HOUSE AT SURBITON.

WE this week illustrate a design by Mr. Rowland Plumbe, architect, of Fitzroy-square, for additions and alterations to a house at Surbiton. The old building had a Doric portico in centre, leading to a staircase passage, with rooms on either side, each having bay windows. Externally it was covered with stucco, the whole being of the ordinary type of speculative builder's work. In the plan of the new house the old dining-room is heightened by the removal of the ceiling, and is turned into a hall two stories high. Round this are arranged a billiard-room, with retiring-room, a new staircase hall, business-room, drawing-room, boudoir, flower-room, and dining-room. The old dining-room is converted into a serving-room and library. The old staircase is made to serve for a secondary staircase. The kitchen offices are on the basement, and there are three floors of bedrooms above the ground floor. Externally, the old building is nearly surrounded by the new. The old roof of slate is removed, and a new porch and bay-window nearly cover the remainder of the old work; but in places where the stucco work would have shown, it has been brought into harmony with the new building by being covered with a red brick casing on the basement and ground floor, and with tile hanging above. A new tile-roof is put on, spanning the whole width of the buildings. The materials used are red brick, relieved by tile hangings and half-timbered work, old tiles being used for the roof. The estimated cost is £7,000.

FOLIAGE FROM AMIENS—ROYAL ARCHITECTURAL MUSEUM SKETCHING CLUB.

THESE interesting examples of foliage from Amiens Cathedral are worthy of the closest study, and our drawings to-day, which have been selected from the sketches of the members of the Royal Architectural Sketching Club, show the designs both truthfully and well, with the advantage of having been finished in pen and ink at the Museum from the casts there, which are almost equal to the original works. The drawings are by Mr. T. Fredk. Pennington, to whom the Council of the Museum awarded their annual prize of five guineas last year for the best series of sketches made during the session in connection with the club. Particulars of the club may be obtained of the curator, at the Museum, Westminster. Other drawings by other members will from time to time be given in our pages as space may permit.

CHURCH OF ST. MICHAEL AND ALL ANGELS, BEDFORD-PARK.

WE have already briefly referred to the interesting and unusually picturesque church of St. Michael and All Angels, Bedford-park, in our "Office Table" notes the week before last; and to-day, in obedience to the promise then made, we illustrate the building by a series of working drawings, which include the three main elevations, two general sections, with two minor ones of the porch. These will be followed by others, including the plan, which shows the church to consist of a rather wide nave, having aisles on either side, a chancel and organ chamber, with vestry beyond, and a large south porch at the western end. The chief interest, however, in the design, which is characteristic of its author, is not found so much in its plan as in the architectural style employed. The drawings will explain themselves. The materials to be used are brick for the walling, with stone dressings, and cut-brick cornices and gables. The roofs are covered with tiles; and the woodwork externally will be finished in white. Internally the woodwork will be painted a sage sort of green, and the sanctuary will be hung with embossed gilt leather. The bases and lower parts of the columns to the nave arcade will be covered with dado panelling to the height of the dwarf wall of the chancel screen, which is seen in our "section looking east," which we publish to-day. The walls of the aisles and chancel are also lined with a wooden dado. The pretty treatment of balconies in the sort of triforium is hardly clear without the longitudinal section which we hope to give next week. They are, however, shown in section, in a drawing herewith of the nave. The work is to commence in

a week or two, and it is hoped that the church will be consecrated before the end of the year. The site occupies a commanding position at the entrance to the Bedford-park Estate, at the end of the Woodstock-road, and to the right of the Turnham-green railway station. Trees are already planted, and with the picturesque new houses, and row of fine old poplars to the rear, the church will have everything to gain from its position, for which it is so well suited. Mr. R. Norman Shaw, R.A., is the architect of the work.

DAIRY HOMESTEAD.

THE agriculture of Great Britain is just now in a transition state. An improved and rapid means of transit brings the agricultural products of all nations into direct competition with those of our own country; hence the breeding and rearing of stock and the production of milk is a more profitable industry than the growth of cereals. The great retarding cause of the expansion of the system is the general want of suitable buildings for the preparation of the food and shelter for the stock. The improved method of management which now obtains renders the erection of large expansive barns no longer a necessity. In the designing of farm buildings economy of labour is an important essential to be considered. Shelter and warmth are food economisers; hence the practical utility of covered yards. In the accompanying design we have endeavoured to combine utility and economy. Stores and food-preparing departments are centrally situated, and have direct communication to all parts of the yard by means of a tramway. As far as practicable, all the internal fences or divisions are constructed of tubular iron. After many years' practical experience we find these both economical and efficient. The rain water from the roofs is conducted through the hollow columns on which the roofs rest, into separate drains, and flows into a brick tank, from which the steam engine directly draws its supplies. The farmhouse, labourers' cottages, and covered hay-barns are conveniently situated.—G. M.

The great increase in the population of the district of St. Mary's, near Southampton, mainly attributable to the establishment in its midst of the shipbuilding works of Messrs. Oswald, Mordaunt, and Co., has led to the formation of a burial board. An excellent site having been obtained, the board issued invitations to the local architects to supply designs in competition for the chapele, entrance lodge, and laying out the cemetery, the result being the selection of the design marked "Gabriel Grub," the author of which proved to be Mr. W. H. Mitchell, of Southampton. Tenders were received both for laying out the grounds and erecting of the buildings by the board at their meeting on Tuesday week, when it was decided to carry out the work forthwith. The total cost, including site, is estimated at £3,000.

The thirteenth annual report of the Cork Improved Dwellings Company, presented at the meeting held yesterday, shows a net profit to revenue account, allowing of a dividend of 6 per cent. per annum being declared, and the carrying forward of £530 17s. 4d.

The Carmarthen Board of Guardians discussed, a fortnight since, what steps should be taken as to providing additional workhouse accommodation, the Local Government Board inspector having insisted on the necessity for erecting a separate block for 40 or 50 children, including dormitories, day-rooms, and lavatories. The vice-chairman (a Mr. Williams) suggested that the cost of plans for such a building need not exceed £5, and proposed that they advertise for plans and offer £5 for the best. The chairman and others protested that such a course would not be true economy, and after much discussion it was decided to advertise for tenders for the execution of the work, the majority of the board being under the impression that no addition will be made to the cost by expecting the contractor to provide his own plans and specification.

The School Board for St. Mary Extra (a district separated from Southampton proper by the river Itchen) recently advertised for plans in competition for a school for 350 boys and master's residence. Eleven sets of plans were sent in under motto. The design marked "Clansentum," by Mr. W. H. Mitchell, architect, of Southampton, was selected. The buildings are to be commenced early in the spring. The tender of Mr. J. W. Rowland, a local builder, amounting to £2,770, exclusive of school fittings and furniture, has been accepted. The estimated cost, including architect's commission, purchase and conveyance of land, fittings, &c., is £3,800.

ST. ALBAN'S CATHEDRAL.

THE controversy regarding the roof of St. Alban's has already reached the quarterlies. The *British Quarterly Review* has an article, in which Mr. Neale's book is taken as a text for a sermon on "Restorations." Everybody is preached it, all round, pretty vigorously except Mr. Neale himself, who is declared to be the "one gentleman" who "has proved himself to be exceptionally qualified" "for the guardianship of this great church."

If the author of the article is the architect whose initials appear on the illustrations which accompany it, we have yet to learn why his professional brethren are so ruthlessly assailed. Certain it is architects are only less roughly handled than the clergy. The latter—"mere sciolists, and mostly ignorant"—have patronised "the wholesale manufacturing men of business," and the result has been the ruin (the restoration that is) of all the "historic monuments" (the parish churches and cathedrals). Sir Gilbert Scott is once more attacked, and two illustrations and several pages of matter are devoted to an exposure of some of his real or supposed mistakes. Mr. Beresford Hope is an "intrepid physiologist" who has proclaimed "with comical presumption his peculiar architectural ignorance," while Sir Edmund Beckett is "meddling with other people's business" in endeavouring to substitute "modern vamping" for the original work of John De Cella at St. Alban's. Yet a little further on the Society of Antiquaries is snubbed for its opposition to the proposed high-pitched roof, which is declared to be "perfectly legitimate," although in its execution "no 'architect' should be allowed to deface the church with his professional designs."

A dissertation on the sin of "modern ritual display" seems to have been dovetailed into the article to keep up the Dissenting character of the *British Quarterly*, and we are treated to a new and original explanation of the causes which induced its author to frame the Mosaic ritual. Moses, it seems, had solely in view the improvement of Jewish agriculture by means of the system of first fruits and sacrifices. Anglican ritualism, whatever its merits or demerits, is probably little likely to benefit British beef, and so commends itself badly to an Evangelical Englishman.

After a good deal about the Parthenon, the Elgin marbles, and St. Paul's Cathedral—which building, we are assured, "is mechanical," and if destroyed might probably be restored better than it was originally built—we come back to St. Alban's. Our only course at present is to let the abbey alone, first because "nature has garnished" its "unbadaled exterior walling," and next because we have neither architects nor workmen fit to undertake the work. It is admitted that the exterior of St. Alban's is "possibly decayed," but this "is no misfortune; it helps nature, and the church has thus acquired a genuine consecration." Gothic works, indeed, seem to have been specially designed with a view to their eventually becoming picturesque "ruins;" so great at any rate is the admiration of the *Reviewer* for such remains that it doubtless seems hard that we cannot spare St. Alban's Cathedral yet awhile. Rievaulx and Fountains, and other similar relics of a dead religious system may still be left to the more or less careful guardianship of their owners, and to lovers of ruins who hold picnics within their precincts; but St. Alban's Cathedral, as the mother church of a new diocese, has, we trust, a long life of usefulness before it, and can yet command the services of true architects and artists to fit it for its purpose, who will do their work much, after all, as their mediæval predecessors did theirs, studying first use, and then beauty, or rather making use and beauty go hand-in-hand, unfettered on the one hand by a blind regard for mere decrepitude and decay, because they are old, but on the other hand reverently preserving for future use as living parts of the building—not mere "ruins"—the remains of the works of architects who, for all we know, had the good fortune to be allowed to do their work in peace, undisturbed either by meddlesome or ignorant amateurs.

Nowadays a minimum of knowledge is almost invariably eponymous—this is the *British Quarterly Reviewer's* pet word—with a desire to exhibit it, and thus disputes as to what is best

to be done between men who know their work, which we have said before are perfectly legitimate, and to be desired rather than suppressed, are joined in by people who can do little beyond echoing phrases and opinions they do not understand.

During the judicial examination of a certain unhappy nobleman, now languishing, &c., it was urged by some sympathising friends that he had for so long a time tutored himself to believe that he was entitled to certain property and estates that in the end he thoroughly and honestly considered himself the rightful heir, the lie having seemingly merged into truth simply from reiteration; and so it is, to my mind, with certain persons now hotly discussing questions relating to St. Alban's Cathedral. Interested architects, spurious critics, bombastic amateurs, and Pickwickian antiquaries have for so long a time reiterated that the decay of St. Alban's Abbey would be nothing short of a national calamity that persons possessed of more money than brains have gradually arrived at that conclusion. Many have gallantly fought on paper, and many, having left the fighting to others, have provided the cash to prevent the consummation of so dire a catastrophe. This idea has been further enlarged by Mr. Neale, who, with a patience and a skill much to be admired, has occupied time on an ambitious undertaking, which time might have been employed in securing to us an equally clever record of a far better example of architectural art.

I think, sir, that were an architect imbued with the greatest possible love for art, regardless of whether to the 12th or to the 19th century it owed its origin, and without preconceived ideas as to restoration, to visit St. Alban's Cathedral to-morrow, he might find the following not an untruthful description of its present condition.

St. Alban's Cathedral is a conglomeration of the various styles of architecture which prevailed from the Anglo-Roman period down to the Victorian era, and, with one or two exceptions, they happen to be the very worst representations of the very worst periods of the respective styles, regarded either from an art or from a constructive point of view. The exterior presents one of the most forlorn and wretched examples of ecclesiastical architecture perhaps existing. The brick walls grin in their nakedness and in their shame, clearly showing that the worst of mediæval jerry builders intended to cover them with plaster, but the gods maybe arrested them in the act of their artfulness, and cut them off as such men usually are, or should be, when endeavouring to hide their unskilful work. The windows generally contain the weakest of tracery, the poorest of mouldings, the worst of proportion. To proceed from the detail to the mass, we find an overwhelming brick tower, an elongated shabby-looking nave, with fenestration of the most abject type, and a diabolically monotonous skyline. The interior contains a very beautiful screen, a patchwork shrine, a sad medley of meretricious architecture, an uninterestingly long and ill-proportioned nave, more bad construction, more weak mouldings, flat ceilings of wood—some horizontal, some intended to be—all smeared with pigments, relieved by stencilled monograms unworthy of the lowest music-hall—an ill-begotten accumulation run up by ill-begotten outsiders; and then we are to be told as Mr. J. P. Seddon tells us, that all this is "unique for sheer simplicity of design." Well, so is the architecture of Gower-street "unique," and from the same cause; but even Gower-street has decent brickwork. Who talks, though, of spending thousands of pounds to preserve to posterity the architecture of Gower-street because it is "unique for simplicity of design?" Who talks of putting a high-pitched roof to the Gower-street houses so as to double the monotony of their sky line? But the thing could be done! Get a wealthy resident, with plenty of impudence, and (because he has mixed with a more or less practical builder, and meddled now and then with architecture) with plenty of asseveration that he knows more than all the London architects put together—get him to write a few letters to the *Times* repeating the asseverations, and then let him tell the public that the best thing to be done to Gower-street is to turn out the

residents, stop the traffic, make a schedule of dilapidations, put on a high-pitched roof, subscribe five thousand pounds to the fund, and proceed. Call in an architect with 5 per cent. on the transaction looming in the distance—call in a few old women antiquaries to swear that what is proposed will earn the gratification of an enlightened posterity—that it will make future architects acquainted with the "unique simplicity of design" of the latter part of the eighteenth century, and the thing is done.

Let us, however, for a moment assume that the architecture of St. Alban's was worth preserving, and consider the manner in which the so-called restoration has been carried out. Take the upper parts of the north-west and south-west portions of the walls of the nave. These were, I suppose, the portions which were so many feet or inches out of the perpendicular, and by a combination of theoretical and practical skill they have been set upright—the fact of their requiring this treatment being a little in favour of my assertion as to the unskilful workmanship pervading the Abbey. Well, we may say that the whole of these upper parts have been restored—that is, as a matter of fact, that all is entirely new except as regards the windows and blanks, one or two old voussoirs or arch stones, and as regards the ashlar work a few old pieces. In one case the whole of the head of a window is entirely new, except a stone in the cinque-foil tracery; in another the whole window is entirely new except the mitre or key-stone; in another a large superficial area of ashlar work is entirely new, except two or three stones. Now, what can be urged in favour of this very questionable mode of restoring a work? We may take it, I suppose, that some authority was found for the style and detail of the new work, and why was it not made complete and not injured in appearance—to say nothing of the possibility of decaying germs in the old work penetrating to the new)—by spots of decayed stone indicative of nothing so much as another early restoration, and an acquiescence in the fads of those Pickwickian antiquaries. I cannot conceive an architect spending the money of his clients in this way, when he must know that what he is doing will lead to another and a more or less immediate outlay. If the idea is to make work for an immediate posterity, well and good, but don't call it restoration.

To descend, sir, from such a lofty matter as restoration let us rest again on the upper part of the north-west portion of the nave wall, and consider the rain-water pipes, how they bend. There are three of them, and starting from the eaves they have the orthodox useless heads, then strange bends which cut right across the arch mouldings of the blanks, then the necessary junctions, and finally the straight lengths—one of the most unpractical and unsightly productions to be imagined. And who is responsible for this—the interesting amateur, the architect, the clerk of works, or Messrs. Macfarlane? But who can find it in his heart to grumble when such devotedness is indicated, such a commendable desire to inform the public is shown in the interior of the cathedral? I allude to the formal hacking-off of some of the plastering to show us the Roman brick, and in the case of an arch tympanum to show us berring-bone work. Oh! sir, the interesting female who points these little prettinesses out to visitors nearly shed tears when she proudly rested opposite them and described them, and waited for that responsive heart-beat, that reciprocal throb which she knew must come. I lifted up a prayer for the interesting amateur, and left. I was for once overcome. A sailor and myself formed "the party," and the poor fellow turned round, and when he returned I knew by the moist sleeve and the partially-dried eyes that he was affected as much as—

WM. WOODWARD.

THE NEW LAW COURTS.

THE eastern or Bell-yard block of the new Courts of Law is so nearly completed that the date of its occupation by the officials is only a question of a few days. Since Tuesday the hoarding has been removed from the Strand front, revealing an arcading of much beauty of detail. The arcade in front forms the outer

enclosure of the basement of the building. It consists of a series of clean-pointed stone arches, cinquefoiled internally, and richly moulded, resting upon coupled red Mansfield shafts, placed depthwise, with carved caps and bases, the latter resting upon a moulded plinth or dwarf wall. The wrought-iron railing filling in the opening arc is an exceedingly clever specimen of wrought work, the leafage on the standards and the treatment generally being very characteristic. The arches externally meet in gabled apices, the haunches of the arches being filled in with an open arcaded balustrading. When the stump of Temple-bar has been removed from in front a considerable accession of width will be gained in the Strand at this narrow point. Progress is also being made with the iron-work and canopy of the projecting clock now being erected by Mr. Benson, upon the face of the south-eastern tower. Entering by the archway through this tower, it is seen to be groined in alternate foot-wide courses of red bricks and Portland stone; the central space is filled by a trap-door of oak, foliated in iron. With the exception of a small gravelled drive the area within the railings is flagged, and at the Carey-street end are two flights of eight and nine steps respectively. The boarding has also been taken down on the Bell-yard and Carey-street frontages, which are enclosed by high railings, set on a stone base. The lamp standards are remarkably substantial, and, indeed, heavy in construction; the glazing is of plate glass with bevelled edges, and the faces are subdivided by bars meeting in a circle. The internal area is not so far advanced as that facing Bell-yard. The salient external features of the eastern block were remarked upon and criticised in the course of our descriptions during last year (pp. 519, 565, 584, Vol. XXXIV., p. 156, Vol. XXXV., published May 24, June 7, and August 16, 1878), and we can only in passing allude to the singular diversity in the slightly projecting bays, the massing and grouping, the capricious want of alignment and symmetry in the columniation and fenestration, and the quaint diapering and crisply stiff carving between windows. As the scheme develops the unexpected variations of design and the vigorous ornamentation reveal Mr. Street's characteristics the more distinctly. Entering the building we find fires burning in every room, and active preparations being made for occupation. The block is in five stories, and is planned with central corridor with rooms branching off on either side, communication being provided by staircases in eastern projecting bay of centre and near either end. There are also several lifts. The rooms are of varied dimensions (some of unusual proportions), and will be chiefly used as law offices, with store-rooms in the basement. We note that all the internal walls are plastered and finished with Keene's cement. The ceilings, both in corridors and rooms, are flat arches of Dennett's construction, the lower flanges of girders being often displayed. The centre of block is lighted through a well by a long skylight, framed wagonwise in wood with clear glass. There is also a window at either end, and small railed-in wells at intervals on each side of corridor. The stairs are guarded by open wrought-iron railing, with oak handrail, and at intervals a singular crook ending in a knob springs from the standards, suggesting the idea of a series of misplaced hat-pegs. The rooms are chiefly lighted by three-light windows, all square-headed, with massive stone jambs and mullions. The sashes are filled with plate glass. They are set in lead, with copper frames and trains, and slide very easily. The fireplaces are all open, and have heavily-moulded hoods, mantelpieces vigorously carved and treated with great variety. The jambs are filled with tile-patterns in four colours, supplied by Messrs. Garrad. The gas-fittings are uniform throughout the block, and have an almost archaic stiffness of outline. They depend J-fashion with up-carved ends, and are executed in polished brass, with wrought-iron scrollwork. Above the entrances to the chief rooms is an acutely-pointed hood-moulding. The doors in the principal room are of oak left unvarnished; in the other rooms they are of deal, painted in two neutral tints for styles and panels respectively—

in some portions of the block in chocolate and red, in others in two shades of sage-green or brown. The door fittings have been made for the contractors, Messrs. Bull and Sons, from the architect's designs, by Mr. Lever, of Maidenhead. The wrought-iron work throughout is by Messrs. Potter. The principal apartment, and certainly one of the most pleasing in the block, is the suitors' waiting-hall, situate on the "court level" at the south-eastern angle of the building. It is oblong in proportion, and opens from the corridors by an open arcade. Above, another arcade, also on two sides, converts a portion of the corridors on next floor into a gallery. These arcades are carried on stone circular shafts with square caps and abaci canted off at the angles, and served with bold First-Transitional foliage, each differing from the others. The roofing is of oak, boarded, with principals, purlins, and rafters displayed, and at the north-west angle of the room a portion of corbel of an external turret protrudes with piquant effect. The room is heated by a coil of pipes encased in interwoven cast-iron work case, like a mediæval chest, as well as by an open fireplace. Ample lavatory accommodation is provided on each floor; the fittings are by Jennings, of Lambeth.

Leaving this completed block, there is considerable progress to be seen to the westward in the main buildings. The stone cutting machinery and stone carvers have been steadily at work throughout the winter, and Messrs. Bull have a large quantity of material stacked on the ground, ready for use, as the weather permits. In the yard we remarked that the stones are numbered and lettered as they are dressed, and these figures are entered into a book, together with the places where they are stacked, so as to allow of easy finding by this key. Returning to the buildings it may be observed that the connecting blocks on the north and south fronts to the west of the Bell-yard block are nearly ready for roofing in, and the next block has almost attained its full height. The great central hall has been carried to the springing of the groining, and the ranges each of eleven buttresses on external side walls have received their copings. The narrow proportions of the hall in relation to its length and height are more apparent as the work proceeds. By the way, a comparison of dimensions with the apartment suggested by legal associations—Westminster—shows that, whereas the hall in the new Palace of Justice exceeds the more ancient one by 2ft. in length, it falls short in width by 18ft.—the accepted measurement of Westminster Hall being 228ft. long by 66ft. wide. The window and wall shafts as fixed are of Portland, but others of red Mansfield, granite, and Purbeck are to be added. The windows are set in pairs in nine bays, and will be filled with tracery. This hall will be approached by groined corridors, now nearly complete, leading to decagonal and circular flights of stairs—six in number—each with an internal staircase for officials within the newel. All the stonework for the hall is prepared in readiness for setting. The range of offices on the Carey-street front have advanced to the third story, and the work generally throughout the vast area is in steady progress, as indeed ought to be the case, seeing that from a thousand to twelve hundred men are constantly employed on the works.

THE STATE OF TRADE AND THE LABOUR MARKET.

TWO very significant sheets of statistics are now before us, prepared under the auspices of the National Association of Master Builders of Great Britain, which speak for themselves. One is a tabular "Statement of the State of Trade and the Labour Market" to January 1, 1879; the other, a "Comparative Statement showing the hours worked per week and the rate of wages per hour in the various Branches of the Building Trade" in the leading towns. Of course, we take them with a certain reserve, for they represent chiefly the masters' account, though we have no reason to doubt they fairly exhibit the state of trade, and the rate of wages in the several towns mentioned, for it will be admitted that master

builders are in a good position to obtain accurate information on such points. In casting our eye down the column "Supply of Labour," we find it to be generally stated as "plentiful" or abundant, while in a few towns, as Birmingham and Dudley, it is described as being "greatly in excess of demand." This is a significant and unfavourable sign, if we can place any reliance upon the masters' view of the matter, which may be somewhat exaggerated, and must be taken with a due amount of caution. At the same time we believe at the present crisis it is fairly representative of the labour market. If we inquire more into detail of the state of trade in particular towns we find the average condition to be slack or depressed. At Aberdeen it is "fair, but prospects not bright;" Ashton-under-Lyne, "quiet;" Birmingham, "very bad;" Bradford, "bad;" Bristol, "very slack;" Barnsley, "bad;" Blackburn, "slack;" Chatham, "dull;" Edinburgh, "very depressed;" Liverpool, "very bad;" Leith, "fair;" Leeds, "depressed;" Manchester, "slack;" Nottingham, "slack;" Oxford, "dull;" Portsmouth, "good;" Southampton, "very slack;" South Shields, "quiet;" Wolverhampton, "very bad;" Wigan, "slack;" and York, "bad;" and these represent the general tenor of the replies. If we further inquire in what branch of trade these remarks are intended to apply we find in every case the portentous adverb, "all" affixed with a few exceptions. Thus in a few places plumbers, plasterers, carpenters, and joiners have a fair amount of work. Referring to another column, in which alterations in the rate of wages and hours of labour are recorded, we find that at Birmingham a notice to all branches is given to increase three hours per week in summer, and overtime to commence one hour later. The operatives have given a counter notice to resist increase of hours and to make demand for increase of pay for overtime. At Bradford employers have given notice to masons and bricklayers to pay 8d. per hour all the year round, the pay coming into operation on June 2, 1879; to carpenters and joiners for a reduction of ¼d. per hour; to plasterers to pay by the hour and ¼d. less, and also to labourers. At Bristol the employers have given a six-months' notice to all skilled trades of a reduction of ¼d. per hour. At Bolton 1d. per hour reduction and increase of one hour in time is contemplated; at Blackburn most of the trades are required to increase the hours to 54 in summer; and similar notices have been given at Chorley, Derby, Doncaster, Inverness, Liverpool, Lincoln, Leeds, St. Helen's, Wolverhampton, Warrington, and other places. In London we find the only branch in which labour is not abundant is that of plasterers. Comparing the hours worked per week and the rate of wages we may take a few representative towns. These are classified under the several trades, summer and winter hours, and wages. Taking Bradford, we find the hours worked by masons per week in summer time are 49½, and the rate of wages 35s. per week; in winter the hours worked are 46, and the rate of wages 33s. per week. The same rates are recorded for bricklayers. For carpenters and joiners the hours are 49½ both summer and winter, and the rate of wages 8d. per hour. For plasterers the working hours are 49½ in summer and 47 in winter, the wages being 33s. per week. At Birmingham the masons work 54 hours per week in summer and 50½ in winter; the rate of wages is 9d. per hour. The same hours apply to bricklayers, carpenters, and plasterers, the wage being in all three cases 8½d. per hour. With slaters it is by piece work. At Coventry masons work 56½ hours in summer and 51 in winter, and are paid at the rate of 8d. per hour; bricklayers work the same, at 7½d.; carpenters the same, at 7½d. in the summer and 8d. in winter; and plasterers the same, at 7½d. At Liverpool the hours worked are 49½ in summer and 47 in winter for masons, and they earn 9d. per hour; bricklayers work 55 and 47½ hours respectively, and earn 9d.; carpenters and joiners, 55 hours, and earn 8½d. In London the following is the return:—For masons, 52½ hours summer, 48 hours winter, earning 9d. per hour; bricklayers—the hours are 52½ and 48 respectively, and the wage 9d.; carpenters and joiners—52½ hours all the year round, at 9d.; plasterers—52½ and 48 hours, at

9d., and slaters the same. Taking a southern town—Southampton—we find the return for masons is 56½ hours all the year—the rate of wages 7d. per hour; for bricklayers it is 56½ and 54 hours, at 6½ to 7d. per hour; for carpenters and joiners it is 56½ hours all the year, and the wage 7d.—remarkably low rates of wages, though at Winchester it is even less, being 5½d. per hour for carpenters and joiners, and the hours 58½. At Sheffield there has been a building trade dispute for some time past, but there is no return made in the tabulations. We hear that lately the masons received a four days' notice for a reduction of 1d. per hour for banker hands or cutters, and 1½d. per hour reduction for wallers. Previous to this the masons' wages were 9d. per hour for the whole year. We leave these facts to tell their own tale, and we trust the workmen will profit by the experience of the last few months, and endeavour by a timely action to check the increase of foreign competition that is now seriously threatening them. The matter will rest with them chiefly.

BUILDERS' IRONMONGERY—WHERE IS THE TRADE GOING TO?

"A WILLENHALL locksmith once assured us" (says the *Echo*) "that in some of the workshops in his town, where the cheap rubbish was made for the use of speculative builders, if a workman dropped a lock as he was fitting it together he never stopped to pick it up, as he could make another in less time. That this slipshod style of manufacture is at length bringing about the inevitable result—loss of business—is evident from a letter written to a morning paper by Col. Wrottesley, founded upon a report made for him by Mr. James Hill, of 37a, Upper Thames-street, London, a large contractor for locks to the War Department. Mr. Hill, who used to have all his locks made at Willenhall, now sends the bulk of his orders to America, so that at the present time our Government buildings—barracks, military hospitals, &c.—are being fitted with locks made in the United States, better and at lower prices than the British manufacturer can produce them. Mr. Hill carefully investigated matters for himself during a visit to the United States before making the alteration referred to, and the causes he assigns for the fact of American productions being cheaper and better than those made in this country deserve careful attention, both from masters and men. In the first place, the Americans employ machinery much more largely than we do; secondly, both masters and men on the other side of the Atlantic are better educated, both generally and technically; thirdly, the men work longer hours; fourthly, there is less drunkenness there than here; and, fifthly, there are fewer "garret masters," the larger number of concerns being limited manufacturing companies with sufficient capital to command brains and to make experiments, which small masters in the Midland Counties, working from hand to mouth, cannot do. There is, indeed, one cause—and apparently one alone—of the present depression with regard to English locks which is creditable to us as a nation, and that is due to the action of the School Boards, which have most properly compelled the attendance at school of the boys and girls who have hitherto been the human machinery of the English lockmakers. Mere children, who could hardly stand or walk—many of them, in fact, had to be strapped to the benches—were formerly employed in the shops; but during the last few years lads and men have had to be substituted, prices have risen in consequence, and this has helped the Americans to undersell us in our own and our colonial markets. As it is with locks, so Mr. Hill declares it is with watches, guns, and tools. The instances given by him of American superiority with regard to mechanical production generally appear to be reliable, and are certainly ominous of the speedy loss of our old manufacturing reputation, unless the lesson they teach is seriously taken to heart."

We have ourselves seen the locks to which the *Echo* alludes, and with the appearance of which our readers are familiar. They are undoubtedly superior to many English locks, of

the same value, in finish, accuracy of the working parts, and quality of material. There is no reason, however, why British locks should not be made to equal them in every respect, and we consider that Mr. Hill deserves well of English manufacturers for the attention he has given to the matter.

ARCHÆOLOGICAL & ARCHITECTURAL SOCIETIES.

LEEDS ARCHITECTURAL ASSOCIATION.—Mr. B. H. Thwaite, of Bolton, read a paper before the Leeds Architectural Association, on Thursday week, on "Structures Capable of Resisting Fires." In his remarks, he said it was surprising with what indifference the question of making buildings fire-resisting was viewed by the profession and the public. The first question generally asked after the intimation of the existence of a fire was as to whether the building was insured, and if the answer was in the affirmative sympathy was rarely expressed. People invariably consoled themselves when erecting buildings non-fire-resisting (to save a little extra expense) with the fact that for a trifle the building could be insured. Now the subject was too serious to be treated with such nonchalance, and was even worthy the attention of the legislature, when it was considered that every building destroyed by the ravaging element represented so much labour (and occasionally lives) irrevocably lost to the nation. On an average the property annually destroyed capitalised equalled three-quarters of a million sterling, equivalent to the annual labour of 10,000 skilled artisans and labourers. This fact alone should influence architects as to the importance of impressing on their clients the desirability of erecting fire-resisting structures.

SOCIETY OF BIBLICAL ARCHEOLOGY.—The annual meeting of this society was held at 9, Conduit-street, W., on Tuesday week, the Rev. Canon Beechey in the chair. The report for the past year commenced with obituary notices of the late secretary (Mr. W. R. Cooper), Mr. Joseph Bonomi, Professor Charles Seager, the Hon. C. W. Goodwin, and others. 90 new members were enrolled during the year, making a total of 539. The total receipts, including £123 from the sale of "Transactions," were over £725, and the expenditure, £572, leaving a balance of £153. The report having been adopted, a communication from Dr. Jules Oppert, professor of Assyriology at Paris, upon the Babylonian contract tables, was read by Mr. W. H. Rylands. The digest of the paper was the difference between the "contract tables"—a large special class of cuneiform documents—of Babylonia and Assyria. The latter are of a far less technical character, as befitting a more practical and not so litigious a people. They are, for the most part, written after an almost stereotyped formula, so that to know the legal form of one perfectly is to know all. On the contrary, no two of those written in Babylonia are framed exactly on the same legal model. Moreover, although the words and sentences are no more difficult to render than those composed in the sister dialect of Assyria, the whole is of so lawyer-like a cast as to make the meaning exceedingly obscure. Professor Oppert illustrated his distinctions by translating and commenting on a couple of Babylonian contract tables hitherto unpublished—one the property of a private gentleman at Paris, and the other in the Louvre collection. Both belong, like great numbers in the British Museum, to the archives of the great Babylonian banking firm of the Egibi family, the Fuggers or Rothschilds of that city, from Nebuchadnezzar's reign till late into Persian times. The former of the two relates to the sale of a field yielding five-sixths of a hemicorion (about 26 gallons) of corn for two mine, one drachma (say, £1 7s.). It bears date from the city of Bit-Aburim, on the 4th of Tisri, in the first year of the reign of Nabonidus, King of Babylon. The second is the succession settlement of a deceased bankrupt, a composition of three mine, seven drachmas, being accepted by the creditor for seven mine. It is dated at Babylon, on the 16th of Elul, in the third year of Cambyse, King of Nations.

Building Intelligence.

CASTLE-FFROME.—Castle-Ffrome church, Herefordshire, is about to be reopened, after restoration under the direction of Mr. Martin Buckle, architect, of Great Malvern—Mr. William Porter, of Malvern Wells, being the contractor. The tower, spire, and porch were found to be in a most dilapidated condition, and have been entirely renewed, the old lines of the former half-timbered ones being strictly adhered to. The roof also has been renewed and restored to its original pitch, and the old oak ceiling beams cleaned and repaired, and the panels filled in with pitch-pine boarding. A new vestry and heating chamber under have been added. The plaster has been taken off the inside, and the old Norman walls repointed. Encaustic tiles have been laid in the chancel, and the whole church has been recast throughout. This church contains one of the finest specimens of Early Norman fonts in existence, and which has carefully been preserved, and also some missing parts found during the restoration, in an old tomb, have been refixed.

DUNOANNON.—Some time ago a destructive fire reduced the premises of Messrs. Stevenson and Aiken, Church-street, Dungannon, to ruins. New shops and warehouses have been erected on the site, and the first portion of these was re-opened a fortnight since. The buildings cover an area of 90ft. in breadth by 120ft. deep. The first story of the street front is executed entirely with local white stone, partly dressed and polished, the spandrels and spaces being filled in with hammered stone. The upper portion of the front is supported on stone piers, with engaged shafts and angles, having moulded bases, bands, and caps, continued through piers. The windows are square-headed, with moulded circular spandrels. The roofs are high pitched and covered with ornamental tiles, surmounted with wrought-iron finials; five dormers break into the chief slope. The shop sashes and doors are all executed in rich pitch-pine, moulded and varnished, the glass being polished British plate, protected by revolving shutters. The work has been carried out by Mr. William Gabbey, builder, Belfast, from designs supplied by Mr. William J. Gilliland, also of Belfast.

DUNSTER.—A new Wesleyan chapel and schoolroom were opened at Dunster, near Taunton, on the 26th ult. The buildings are Italian in character, and have been erected from the designs, and under the superintendence, of Mr. Shewbrooks, of Taunton. The fronts are faced with Williton stone laid in courses, with bases, pilasters, quoins, copings, and other dressings in London cement. The roofs are covered with slate with red cresting. The chapel internally is 31ft. by 26ft., and 30ft. high to centre of ceiling. It has sittings for 252 persons, having sloping backs and seats, and solid moulded pitch-pine ends. There is an apsidal chancel, 17ft. 6in. by 14ft., raised three steps above the general floor level, and at the end a wheel window 8ft. in diameter, filled with stained glass executed from the architect's drawings by Messrs. Fournere and Watson, of Plymouth. To left of chancel is choir chapel, and to the right the minister's vestry, 15ft. by 13ft., with boiler-house attached. On the right-hand side of chapel, with separate entrance, is the schoolroom, 33ft. by 13ft., above a room open to the chapel, thus serving a double purpose as class-room and gallery. The building contract has been carried out by Mr. Templeman, of Taunton, at a cost of £950.

FULBOURN.—The 21st annual report of the committee of visitors to the Cambridge-shire and Isle of Ely Pauper Asylum states that since 1876 the following works have been carried out at the asylum at Fulbourn, near Newmarket, under the superintendence of Mr. K. R. Rowe, asylum architect:—On the female side—a day and night infirmary, a laundry, patients' day-room, boundary wall and gates, general w.c.'s, general bathroom, corridor connecting with wards and infirmary, and others to female entrances on north and laundry dry-room, extension of east day-room on ground floor, and widening of front day-room and

sleeping-room over it. On the male side an infirmary and general w.c.'s. The cost has been about £8,000. During the present year a new dining-hall and recreation room will be built.

HANLEY.—The first of the new Board Schools erected by the Hanley School Board was opened on the 13th inst. These schools are in three departments, all on the ground floor, and the general plan is in the form of an inverted L. The boys' and girls' department form the head of the letter, and each comprise a main room 60ft. x 22ft., with three class-rooms 22ft. x 18ft., fitted with galleries for dual desks and sliding partitions. Externally the schools are executed wholly in brickwork and tiled roofs, and the style adopted is the Queen Anne type of a plain character. These schools provide for 754 children—namely, seat accommodation for 250 boys and 250 girls, and 254 infants on the St. basis. The cost of the buildings is £6 1s. 7d. per head; cost, with the site, £8 1s. 3d. per head, and the cost, including dual desks, furniture, architect's commission, and other expenses, £8 18s. 10d. per head. The works have been carried out by Mr. George Ellis, builder, of Hanley, under the superintendence of Mr. W. A. Keates, architect to the board.

LONDON SCHOOL BOARD.—At Wednesday's meeting of this board the amended tender of Messrs. G. Ward and Son, of College-road, Dulwich, amounting to £5,978, was accepted for the erection of a school for 600 children in Salter's-hill, Lower Norwood. Various alterations were sanctioned in schools in Cottenham-road, Hornsey-road; Hughes's Fields and Canterbury-road, Deptford; and St. Paul's-road, Bow-common, at a total cost of £600. The appointment of Mr. A. Young, as assistant surveyor, was confirmed for 12 months; it was stated that this officer would then quit the service of the board, as he has entered into private practice. The works committee were authorised to nominate for appointment by the board an additional officer, whose duty it shall be to furnish estimates of the "provisions" in the tenders, and on the completion of the works to measure up all additions to, variations in, and omissions from the contract, and to settle the final accounts; such officer to rank as a principal clerk under the scale, at a commencing salary of £300 per annum. The same committee was authorised to make arrangements for the appointment of an additional clerk in the architect's department.

METROPOLITAN BOARD OF WORKS.—This board, on Friday, received a deputation from the St. Luke's Artisans' Dwelling Scheme Association, who presented a memorial on the subject of the Whitecross-street improvement scheme. The deputation represented that two years had passed since a scheme was commenced for the wretched and densely-peopled district, and that there appeared no prospect of progress, although isolated pieces of land had been acquired. It was stated by members that the blame did not rest with the board, but was due to the cumbrous provisions of the Act, which rendered it almost impracticable and very expensive. The memorial was referred to the works committee, and a hope was expressed that as the attention of Mr. Home Secretary Cross had been called to the defects in the Act some amendment would be made. Messrs Mowlem and Co. were instructed to re-lay and repair the stone tramway on Stratford-bridge at a cost of £590. The works committee submitted for approval of the board inscriptions to be placed on the pedestal of the Obelisk, as settled after consultation with Dr. Erasmus Wilson and Dr. Birch, of the British Museum. These were read and approved, and it was referred to the committee to carry them out at the entire cost of the board. The Plumstead District Board were informed—in reply to their letter, inquiring what steps the Metropolitan Board propose to take in order to prevent the pollution of the river Thames by the sewage at present cast into it, and urging the necessity of adopting some system of deodorising the sewage, and of utilising it in the cultivation of waste lands—that the board were not at present in a position to adopt the course suggested in their letter. It was decided to place a fire-escape on Shepherd's-bush Common, for the protection of the neighbour-

hood, and drawings prepared in the superintending architect's department were approved for a new fire-brigade station, to be built in Grove-street, Greenwich.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post-free 24d. Office: 31, Tavistock-street, Covent-Garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the **EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.** Cheques and Post-office Orders to be made payable to **J. PASSEMORE EDWARDS.**

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—S. Bros.—M. B.—B. of D.—G. T.—D. J. F.—W. O. C.—G. W. and Son.—J. K.—F. W. R.—C. L.—B. S. and H.—J. A. and Son.—R. S. and Co.

W. M. ABSTON, Glasgow, and **H. J. Badenoch**. (Mr. Rawlinson's "Suggestions," a notice of which we gave on the 3rd January, may be obtained of Knight and Co., 90, Fleet-street, Harrison and Sons, 59, Pall Mall, or Edward Stanford, 6, Charing-cross. The price is 3s. W. L. N. (We have found it answer well.)—J. L. (1. Write to B. T. Batsford, 52, High Holborn. 2. All particulars can be obtained from the respective secretaries. You will find those concerning the R.I.B.A. advertised in our own pages.)—J. M. BAYDON. (Next week.)

"BUILDING NEWS" DESIGNING CLUB.

LIST OF SUBJECTS.

1. A group of three cottages, two having 4 rooms and one having 6 rooms, with wash-houses and other offices to each. Style to be suited to a rural locality. Estimate to be based on 6d. a foot, cubic. Scale of drawings to be 6 feet to the inch.—2. A pulpit in stone, detached for a small and simple parish church. Inch scale, and details 1/2 full size.

DRAWINGS RECEIVED.—Ich Dien, In with Leeds, Cyprus, Nemro Burswell, "To be or Not to Be," "I New Year's Day," Signum, "Be to its Merits very Kind, &c.," W. G. M. in circle, J'espero, Ognore, Corvus, Try.

RECEIVED.—Arthur Marshall, W. W. Bond. (The rules were published in the **BUILDING NEWS** on Sept. 20th last, and you may obtain a copy by enclosing stamps to the publisher.)

Correspondence.

BELHAVEN CHURCH, GLASGOW.

To the Editor of the **BUILDING NEWS.**

SIR,—The remarks of your correspondents on the design for Belhaven Church appear to me to display a very superficial criticism. With exception of the two matters of the great altitude of the front and the standpoint of the perspective, there is really not any point of resemblance worthy of remark. The plans are altogether different—one is a large, the other a very small edifice. The management of the details in both the buttressing and windows and arcading is such as to make the artistic effect of the two something quite different. The monster buttresses and heavy pinnacles, the three large lights crushed between them, the centre pillar carved down to the lowest string, have the unfortunate effect of making the front, as a whole, a very heavy-looking affair, altogether lacking not only the rich design, but the graceful proportions of the several details in Mr. Shaw's design.—I am, &c.,

CRITIC No. 3.

PENMAENMAWR, OR BLUE WELSH STONE.

SIR,—Will you permit me, through your columns, to call the attention of borough engineers and town surveyors to a most disingenuous attempt to mislead them, which has been made by the Nevin Granite Company, Leadenhall-street, London?

About eighteen months ago I was desired to report upon the suitability of several classes of stone for paving purposes in the borough of Bradford. Amongst these happened to be some Penmaenmawr, or blue Welsh, respecting which great complaints had been made. A copy of my report the Nevin Granite Company have somehow obtained, and it appears to have occurred to them that it would be exceedingly smart were they to take a few words here and there from the report and put them together in such a fashion as to make me give a favourable account of a paving material I had distinctly condemned, and transfer this to the granite they supply. That they have done this deliberately, and with full knowledge of what they were doing, is apparent from the fact that they pass over half a page of my report condemnatory of the Penmaenmawr stone, and pick out the concluding half of a sentence, the beginning of which did not suit their purpose, and use it to give a false colour to the statistics which were appended to my report.

I append for the comparison of your readers that part of my report from which the quotations are taken, and the statement in the Nevin Company's circular. Such a mode as they have adopted of puffing their granite seems to me to merit strong condemnation. If official reports are to be tampered with in this manner for advertising purposes, injustice will be done to the reputation of those whose duties are already sufficiently arduous, and there will be no reliance to be placed upon even the most positive statements put forward by those interested in the supply of any particular material. I am quite aware that most firms are too honourable to condescend to so reprehensible a course of action as that taken by the Nevin Granite Company, but in order to aid the former in maintaining their position it is desirable that wrongdoers should, when detected, be exposed.

The following is the passage in my report:—

It is now upwards of twelve years since you commenced to pave with granites, and during that time five varieties of granite have been tried: they are—

- 1.—Penmaenmawr, or blue Welsh.
- 2.—Mountsorrel.
- 3.—Dalbeattie.
- 4.—Shap.
- 5.—Random.

No. 1 is the 3in. by 5 1/2in. Penmaenmawr, or blue Welsh Sett, as laid down in Thornton-road, Tyrral-street, and part of Market-street. This is by far the most durable stone of any in use here, but from its extreme hardness it is liable to become slippery, and terms an exceedingly dangerous pavement, and one not suitable for use as a paving material. Some of this stone has been laid down about twelve years, and I am unable to detect that it is yet worn to any appreciable degree.

I may, however, state that the quality of the Welsh granites laid down in Bradford is not that which is best adapted for paving purposes. A quantity of this granite, which was laid down for crossings a few years ago, has recently had to be taken up, and in the course of some correspondence with the company supplying it I was informed that the stone was supplied as channel runners—not as crossing stones. This must not be regarded as a fair sample of Welsh granite, for an abundant supply can be obtained out of the grey rock, equal to the Mountsorrel and Dalbeattie granite, both as respects security of foothold, cost, and durability. Large quantities of this grey granite are being used in Manchester and Liverpool, where it gives great satisfaction.

What the Nevin Company's circular makes of this is:—

The following extract from a special report upon the subject of granite paving, made by the borough surveyor of Bradford, Yorkshire, at the request of the Street and Drainage Committee, shows the relative value of Welsh granite as compared with some other descriptions used for paving in that borough. The surveyor's experiments and calculations are based on a period of 25 years and an area of 7,000 superficial yards. In reference to the Welsh granite he says: "An abundant supply can be obtained out of the grey rock, equal to Mountsorrel and Dalbeattie granite, both as respects security of foothold, cost, and durability. Large quantities of this grey granite are being used in Manchester and Liverpool, where it gives great satisfaction." The following table is the result of the experiments referred to:—

TABLE—Showing First Cost of the different kinds of Paving laid down in the Borough (exclusive of Foundations), with Repairs, Interest, &c., based on a period of 25 years, and an area of 7,000 superficial yards, in Manchester-road, from Tyrrel-street to Mill-lane.

MATERIALS.	First Life in Years.	Area in Superficial Yards.	First Cost.				1st Repairs, including waste.				1st Renewals.				2nd Repairs, including waste.				2nd Renewals.				3rd Repairs, including waste.				Interest at 4 per cent.	Total Cost at the end of 25 Years.						
			Price per Yard.	£	s.	d.	To end of Years.	Price per Yard.	£	s.	d.	To end of Years.	£	s.	d.	To end of Years.	£	s.	d.	To end of Years.	£	s.	d.	To end of 25 Years.										
YORKSHIRE SETTS	8	7000	4/11	1720	16	8	5	2/7	904	3	4	8	1720	16	8	13	004	3	4	16	1720	16	8	21	004	3	4	25	£	s.	d.	£	s.	d.
RANDOM GRANITE	10	7000	5/0	1750	0	0	5	2/	700	0	0	10	4750	0	0	15	700	0	0	20	1750	0	0	25	3990	0	0	10,640	0	0		
SHAP GRANITE ...	9	7000	9/6	3325	0	0	6	3/3	1137	10	0	9	3325	0	0	15	1137	10	0	18	3325	0	0	25	7703	10	0	19,953	10	0		
WELSH GRANITE ...	40	7000	11/0	3850	0	0	12	2/0	350	0	0	25	4032	0	0	8232	0	0				
DALBEATTIE GRANITE ...	18	7000	10/6	3675	0	0	9	2/6	437	10	0	18	1599	6	1	25	3955	0	0	9666	16	1				
MOUNTSORREL GRANITE ...	25	7000	12/0	4200	0	0	9	2/0	350	0	0	25	4424	0	0	8974	0	0				

They give the following statistics, and say—

From this table it will be seen that Welsh granite sets, over an equal given area, last 15 years longer than Mountsorrel granite, and cost £742 less; 22 years longer than Dalbeattie granite, and costs £1,434 16s. 1d. less; 30 years longer than Random granite, and costs £2,408 less; 31 years longer than Shap granite, and costs £11,721 10s. less; 32 years longer than Yorkshire sets, and costs £4,455 less.

The Nevin Company thus appropriate to the grey granite the character for durability I had given to the Penmaenmawr or blue Welsh, and after I had said (on their own representation) that Welsh grey granite was equal in respect of security of foothold, cost, and durability to Mountsorrel and Dalbeattie, they make me give statistics showing that it is both cheaper and more durable than these. They may say that they find the words "Welsh granite" in the table, but the heading of the table which they quote states expressly that it refers to "the different kinds of paving laid down in the borough." I may here state that when my report was written not a single stone of grey granite had been used in Bradford, and on the page of the report from which they quote their introductory misleading half sentence, it is set forth with a prominence that precludes mistake, that the only Welsh stone laid down in Bradford was the Penmaenmawr or blue Welsh. The first sentence of the paragraph from which they take their quotation expressly calls attention to the fact.

The designation "Welsh granite," I may say, was used because the Penmaenmawr stone was known by that name to the Council and the public. The Nevin Company thus represent me as giving the preference to the material I have condemned.—I am, &c.,

JOHN ALLISON, A.I.C.E.

Borough Surveyor, Bradford.

January 10, 1879.

WOLLATON.

SIR,—May I ask for a few lines to acknowledge Mr. Warner's obliging communication about Smithson and Thorpe? I have looked in your pages, August, 1875, for the epitaph of the latter, but do not find it. Can he supply the reference to the page? Neither name nor that of the heading of this communication appears in the index in that half-year volume. Allow me also to ask his attention to the dates given by him of Smithson, who died in 1644, aged 79. He was born, therefore, in or about 1565. Hence, as the house was commenced in 1580, Smithson could only have been 15 years of age! The drawings to which Mr. Warner refers must have been subsequently drawn by Smithson; but could the design have been

made by him? It is curious that the record-room at Wollaton has no document giving the name of the architect-designer, who, as far as we yet know, must have been John Thorpe.—I am, &c.,

WYATT PAPWORTH.

ARCHITECT OR SURVEYOR.

SIR,—I am much gratified to find that I am not the only one who is cognisant of the malpractices of some quantity surveyors, acting in concert and collusion with architects and contractors—the latter being the medium or vehicle through which the disgraceful proceedings are so subtly managed as to baffle the scrutiny of clients, for there never was, I positively assert in the cases to which I refer, a more systematic conspiracy devised to filch money from the pockets of unsuspecting employers than the *trio conjuncto in uno*, spoken of have committed and consummated. Happily for the profession in particular, and society in general, such wrong-doers and base partisans are in the minority.

It is well for men of honour and integrity, and those of unswerving rectitude—and there are scores of such adorning the profession—that the black sheep be excluded from the fold, for "by their works ye shall know them." And in confirmation of the statement of "Old Builder," that in his experience he has discovered the fact "that great frauds are committed, and the helpless clients are kept in ignorance of the impositions saddled upon them by craftily manipulated accounts," I can adduce ample evidence.

With the exclusive object of putting employers on their guard as to their future requirements, and checking those who revel in their ignoble achievements, whilst miser-like they hug the gold they cannot count, beyond the tomb, I have had accorded me the favour of giving publicity in the columns of the BUILDING NEWS to the subject of the quantity surveyor and his percentages, and with that functionary I have associated both architect and contractor, because one is powerless and impotent to act without the other (if I mistake not, three is the licensed number of most vicious fraternities); but whether the architect shared "the spoil" with him in the case I alluded to in my last (whereby the quantity surveyor's aggregate commissions on one contract reached £3,500), I know not. But this I can affirm, that the architect employed him, and that the contractors benefitted in a large degree I can also show; otherwise they would not so readily concur in the quantity surveyor's making out their accounts. But how men, as high-class traders and contractors, having raised themselves to the highest pinnacle of

commercial greatness—having amassed colossal fortunes—can, regardless alike of principle or consequences, mix themselves up with, aid and abet, those plying their illicit trade, is an enigma I cannot solve! The exposé cannot imperil their business existence, but it may act as a deterrent in the future, and if they have consciences and read the BUILDING NEWS, it must make them hide their heads and blush with shame!—I am, &c.,

CONSTANT READER.

SIR,—The letter given in your issue of Jan. 10, 1879, and signed "An Old Builder," does not at all touch "Surveyors." The scandals he brings to light are in each case quoted of "architects" who take off their own quantities. As a provincial surveyor I must say that, whilst I know and deplore the existence of "quacks," both architects and surveyors, who work at any price for their client, and put it on in secret for quantities, &c., still I do not, and will not, believe that any general practice obtains of making such charges as "An Old Builder" mentions. It is high time that clients took care that their architect had nothing to do with the quantities. There is the safeguard—a responsible independent surveyor.—I am, &c.,

PROVINCIAL.

SIR,—I read on p. 688, last volume, last line of second column, and first six lines of third ditto, the following:—

A client engages an architect to prepare designs and drawings, and supervise his building, but he does not for a moment imagine that another 2½ per cent. comes out of his pocket for the preparation of the items or the document on which the builder bases his contract tender.

To this I say that "clients" must be very "green indeed" if they do not know it. They should ask and insist upon a bill of quantities being furnished to them, and they would find the last item to be, after the total is summed up, "surveyor's charges, — per cent., to be paid out of the first amount certified by the architect or engineer," as the case may be. I have seen scores of bills of quantities like this.

MEMBER OF CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7, Westminster-chambers.

WELL-SINKING.

SIR,—Referring to the price quoted in your last issue, on p. 53, for well-digging in chalk—viz., 200ft. deep at 18s. per foot, without brick steining—allow me to inform you that in 1872 I had a well sunk, 3ft. in diameter, and 200ft. deep, for £51 17s. 9d. The price referred to above would amount to £185 8s., the only difference being that the diameter in the latter case is 4ft.—I am, &c.,

London, Jan. 1879.

W. EVE.

Intercommunication.

QUESTIONS.

[5635].—**Water.**—Will some one who knows give an idea of the rate per cent. on contract price paid by builders to water companies in some English centres, and oblige—A SCOTCH BUILDER?

[5636].—**Porous Bricks.**—Can any reader of the BUILDING NEWS inform me if there is a brick-making material to be had that is unusually porous? It would be required for sanitary purposes, and it is essential that water should pass through it under a little pressure, with moderate rapidity.—Z. X. Y.

[5637].—**Land Valuation.**—Would some of your correspondents state what would be a proper charge for valuing a homestead of 40 acres, with a small dwelling and outbuildings, the result being handed to the employer in a lump sum as the annual value, the property valued being a dozen or fourteen miles from the residence of the valuer?—L. H.

[5638].—**Concrete Columns.**—We are about to erect a covered service reservoir, where we intend to use cast-iron columns for support of superstructure, which will be brick arches on girders. The columns will be 11ft. high, and 9in. diameter at top, and 10in. at base. We think of filling the interior of columns with Portland cement concrete, to prevent the space being occupied by water. Can any one inform us, through the medium of your "Intercommunication" column, whether that is the best material for the purpose?—COCKER.

[5639].—**Quarries.**—**Colouring Plaster.**—Can any of your correspondents inform a reader in America where he can procure those small old-fashioned bull's-eye window panes? I recollect they were of a peculiar crystal colour, with a kind of bunch of glass in centre. I would like to know the address of parties where they are to be had, and the sorts and sizes of them. I would also like to inquire the method of colouring or tinting interior plastering to give a washable and non-absorbent surface?—AN INQUIRER, Cincinnati, Ohio.

[5640].—**Jointing Drains.**—Can any one explain why the jointing of drain-pipes in "clay" is considered so very objectionable? The town from which I write this has been re-drained on an expensive and efficient plan about 5 years ago, and the whole of the drains are laid with clay, both to the main drains and the junction drain to houses. It was not done here to save cost. It would have been perhaps cheaper to have done it in cement, as there is no clay in the country, and it had to be brought over 70 miles by rail.—B.

[5641].—**Flues.**—I note in the "Common-place Column" of last week, 9in. square is stated as the full size of a flue, or even 9in. diameter, if circular. Now, the Chimney Sweeps' Act stipulates that no flue shall be less than 9in. by 14in., and this is still in force, for a short time ago the Secretary of State drew the attention of all local authorities to this clause, and in many towns the corporations or local boards communicated with the builders and architects, requiring their attention to the matter. I should be glad to know how this regulation agrees with the general custom of building? I note, too, in Mr. B. H. Thwaites' paper on "Hygiene," that "24 square inches for sectional area of flue is ample." This would be under 9in. square.—B.

[5642].—**Defective Drains.**—Can any of your readers kindly tell me what is the best course to be taken under the present circumstances? In a provincial town a sewer runs under a certain house, in which a clergyman and large family are at present residing. It has often been remarked how very offensive the air is in the lower rooms of the house, especially in the mornings. The town authorities having been complained to, sent up their surveyor, who said that the private connections with the sewer were bad, and that the owner must have them looked at and made perfect. This was consequently done, according to the surveyor's suggestions. The nuisance, however, never disappeared, although not quite so bad. Lately, however, the air has been so impure that the basement floor was again excavated, and two large rat holes were found in the main sewers. The authorities have been again complained to, but without effect. Is there any higher authority that can act in these local matters if complaints are sent? There has been an unusual amount of sickness in the family, and the defective state of drains has doubtless been the cause. Any advice would greatly oblige—A SUBSCRIBER.

[5643].—**Clerical Dress in the Middle of Last Century.**—I possess the figure of a country parson, date about 1750, which I am anxious to restore correctly. He is of somewhat portly form, and wears (like the immortal Wesley is said to have done) "a long-tailed coat all buttoned down before." This has three buttons only, however, and the upper part opens, showing slightly the shirt beneath. Outside the coat, and around the waist, is a buckled leather strap. There are front pockets, with large lapetta thereto, in his coat skirts. He wears the long two-tailed collar common with the clergy when preaching 20 or 30 years ago. A little lower down than the belt, on both sides, is a button. He has knee-breeches and low shoes, with a water-tight tongue rising above each buckle. He carries his hat—a low-crowned and broad-rimmed one—under his right

arm, wears his hair long, has whiskers right round chin and cheeks, and the upper part of his head is covered by a skull-cap. The general costume is that of a Bluecoat boy. The figure, which is 2ft. high, and carved in elm, has stood for more than 100 years over the poor-box at St. Michael's Church, Pinhoe, Devonshire. Successive generations have decorated it apparently precisely as fancy suggested. Before returning it to its original position I should like to paint it correctly, and shall be obliged by suggestions thereon.—HARRY HEMS.

[5644].—**Concrete Arches.**—**Fireproof.**—Will some correspondent who has had some experience with the above kindly give his opinion on the following?—It is proposed to form a fireproof floor by constructing concrete arches (in lieu of brick) on iron girders, on the Deane's principle, thus: Span between girders, 7ft.; rise of arch, 7in.; thickness of concrete at haunch, 9in.; ditto at crown of arch, 6in.; boarded floor over; concrete composed of 1 of Portland cement to 2 of Thames ballast and 1 of sharp sand. May it be considered capable of sustaining a working load of 1½ cwt. per foot super and fireproof? Girders may be supposed capable of doing their part of the work.—NEWCASTLE.

REPLIES.

[5621].—**Strength of Timber.**—The following from "Harst" may perhaps be useful to "J. A. A." Beams, cross section rectangular, supported at both ends:—

b = breadth in inches.

d = depth in inches.

L = length in feet.

W = breaking weight in cwt.

Load in the middle: $W = C \frac{b d^3}{L^3}$

C being the weight in cwt. required to fracture a bar lin. square and 1ft. long.

$C = 60$ ash, English.

45 beech.

36 fir, white spruce.

48 Kauri pine, New Zealand.

35 larch, English.

50 oak, English.

40 pine, Northern, Dantzic, and Memel.

35 pine, Northern, Riga.

50 pine, pitch, American.

40 pine, red, American.

38 pine, white, American.

35 slate, Welsh.

Breaking weight according to mode of fixing.

Applicable to all Beams and Girders:

Beams supported at both ends and loaded in the middle = W .

Ditto supported at one end, and fixed at the other, the load on the middle = $W \times \frac{1}{2}$.

Ditto fixed at both ends, and loaded on the middle = $W \times \frac{1}{3}$.

Ditto fixed at one end, load on other end = W .

Beams in all cases will support double the load when distributed over the length that they would if placed on the middle.—STUD. INST. C.E.

[5630].—**Inscription.**—In reply to "A. B." the inverted commas denote abbreviations. Written at length, the first legend would run: "Cujus Animæ (æ) propit (t) ietur Deus" (To whose soul may God be mercifully disposed). The second—"Mutatis mutandi"—is similar. See Apocrypha II., Maccabees, xii., 44.—J. L. H. S.

[5639].—**Inscription.**—The formula on brasses and monuments means "God have mercy on his soul," and is taken from 2 Tim., i., 18. Thus, on the tomb of Bishop Isaac Barron, at St. Asaph, are these words: "O vos transuentes in Domum Domini, in Domum orationis, orate pro conservo vestro ut inveniat misericordiam in die Domini." He deceased in 1630.—MACKENZIE E. C. WALCOTT.

[5631].—**Sketching.**—First go to Durston Junction on the Great Western Railway, and from thence walk about two miles to Lyng, a small hamlet with an interesting church; then to Athelney, another two miles. Here is a ruined church on a mound; it looks tempting from the "line," but I never visited it. Next proceed to Langport, through Aller. At Langport is a very fine church, with some interesting old glass in good condition, and a small 15th-century chapel perched on a lofty gateway, which I guess to be of the 14th century. Hnish Church has interesting Norman work and a grand tower; and here I wish to direct attention to the rich colour of the Ham-hill stone, which is so much used in the churches and houses hereabout. It weathers splendidly, and acquires a covering of yellow and grey lichen, which is very charming. Near here is Muchelney, with its interesting abbey, ruins, church, cross, and cottages. Long Sutton has a fine church—restored, I am sorry to say, mercilessly—with remarkable rood screen and pulpit. From here to Martock, passing through Long Load and Stapleton. On entering the latter observe, first on the left and then on the right hand side of the road, two battered medieval sculptures built into the walls of some farm buildings. At Martock is a very noble church, principally of the 15th century, but with early 13th-century chancel; a picturesque street, with many good 16th and 17th century buildings, and a most interesting manor-house of the 13th century, almost intact. This should be measured and drawn to scale. Through Bower Hinton to South Petherton. On the bridge over

the Parrett, on the Fosse-way, are two stone effigies worth noticing. There is a local tradition relating to them. South Petherton Church is large and fine, with lofty octagon central tower, some interesting monuments, and a pair of very fine 15th-century brasses. In the town are a manor-house (15th century) and some 17th-century houses with good chimneys; and near is Wigborough Manor-house. On referring to the Ordnance map a group of villages will be seen to lie to the west of Petherton so near together that one is hardly well out of the first before the second is in sight, and so on to the last. Begin with the most northerly ones. Of this group I know that Kingsbury has a good church and a fine tower; Barrington, an interesting church with central octagon tower, and close by is a remarkably fine Tudor mansion (Barrington Court); Shepton Beauchamp has a fine church; Puckington, an interesting church with 17th-century chancel screen; Stocklinch, a small early cross church; Ilminster, a very fine church with interesting and fine brasses. I should then go to Hinton, St. George, and Crewkerne, and back through the villages of Haselbury, Chianock, Chiselborough, Norton, and Stoke. In Stoke are some monastic remains and an interesting church. Ascend Ham-hill for the very fine and extensive view; descend to Mountacute, a picturesque village with remains of priory, a magnificent Elizabethan mansion, and good 17th century cottages; then through Adcombe, Brympton, with fine manor-house, and Preston, to Yeovil. Here is a grand church, in which is a good 15th century lectern, on which observe the engraved half effigy of Martin Forrester, monk, and Latin verses. In Yeovil were also some houses worth sketching. Trent Church should be seen, and then another closely-packed group of villages lying beyond, in several of which I know are churches and other things worth seeing. Cadbury Camp lies in the way, and is worth walking over. Work now to the west through Lydford, Keaton, and East and West Charltons. In the latter are two interesting churches and an old rectory. Somerton may next be visited, where is a fine unrestored church with a singular octagon tower and an elaborately-carved oak roof. In the market-place are a curious butter-cross and some picturesque houses. Walk by the foot-paths across the fields by Littleton, where many Roman remains have been found, to Compton Dundon (from the Beacon-hill is a very fine view over Sedgemoor, &c.), through Street, to Glastonbury; from thence, if time will allow, Baltonsborough, Barton, St. David's, &c., might be explored. From Glastonbury go by rail to Wells, from thence to Shepton Mallet, back to Wells, on to Cheddar and Uxbridge, and through the villages between the last and Yatton, where at Yatton Junction the main line of the Great Western Railway will again be met with. I may just add I do not know all the places I have named, but I have seen most of them, and know them to be well worth visiting. I must also prepare the architect and archaeologist for some disappointment and disgust as he becomes acquainted with the slashing and thorough style of restoration in which the Somersetshire clergy seem to delight.—O. E. S.

LEGAL INTELLIGENCE.

ARCHITECTS AS ARBITRATORS BETWEEN THEIR CLIENTS AND THE CONTRACTORS.—In the Court of Appeal, on Monday, before Lord Justices James, Baggallay, and Bramwell, the case of Wood and Son v. the Bedwelly School Board was decided. This was an appeal by plaintiffs from the decision of Vice-Chancellor Malins, refusing on intervenutory motion an injunction restraining Mr. Blessey, the surveyor and architect of the board, from acting as arbitrator in the settlement of the amounts due to Messrs. Wood and Son under three contracts for building the George Town, Blackwood, and Earl-street schools respectively. The contracts contained the usual clause appointing the architect as arbitrator in cases of difference, but it was alleged that Mr. Blessey had, in the course of the transactions between the builders and the board, shown a bias which disqualified him from the discharge of the duties of that office. The appeal was dismissed, with costs.

PLASTERER v. MASON.—At Lambeth county court, last week, the case of Scudamore v. Hoborn was heard. Plaintiff is a plasterer, and defendant a builder and contractor, of 94, New Kent-road. The claim was for £10 16s. 3d., balance of contract. Plaintiff contracted, at £30 per house, to plaster and cement two houses in Barry-road, Peckham. The dispute turned on two items—for cementing pier caps in one of the houses, and fixing of springers to bay windows. After the contract had been entered on, stone was preferred to cement for one of the houses, and a mason was called in to do certain work. Plaintiff asserted that he performed other work in lieu of that the mason took from him. Judgment for plaintiff, for £8 16s. 3d.

The centre light of the eastern triplet in St. Peter's Church, Parkstone, Dorset, is being filled with stained glass in memory of the late Mr. John Parr. When completed with the side lights the subject will be "The Adoration of the Lamb." The artist is Mr. James Bell, of 98, Great Russell-street, Bloomsbury.

Our Office Table.

THE new edition of Street's "Indian and Colonial Mercantile Directory" is indispensable to all who are engaged in business transactions with the various places referred to in its pages. The list of these include India, Ceylon, China, Japan, the Eastern Archipelago, Java, the Philippine Islands, Australia, New Zealand, Tasmania, Fiji, South Africa, Canada, America, the West Indies, &c., and in each case the information given is well arranged, and is of the most comprehensive character. Various steam routes to the places treated of, with rates of fares and times of transit, are given, thus placing concisely before the public the different facilities offered by the several companies. Particulars of the various railways in operation or construction are also supplied where practicable. The London agents to each of the banks are named, so that a merchant is enabled to see to whom to apply where financial information or assistance is needed in connection with any particular town or city. The number of towns and cities represented has been slightly increased. An important feature is the insertion of maps of the various countries mentioned, in which the relative positions of the principal towns are clearly shown.

Our readers will regret to learn that Mr. E. M. Ward, R.A., who has been for some days dangerously ill at his residence, Osborne-villas, Windsor, died at ten o'clock on Wednesday night. Mr. Ward, who was the nephew on the mother's side of Horace and James Smith, the authors of "Rejected Addresses," was born at Pimlico in 1816. In 1834 he was admitted a student of the Academy, under the auspices of Wilkie. His first picture, a portrait of Mr. O. Smith as Don Quixote, was exhibited in 1834. He went to Rome in 1836, and remained there nearly three years. "Cimabue and Giotto" was the first picture exhibited on his return, but it was "Dr. Johnson reading the MS. of the Vicar of Wakefield," in 1843, that brought him into public notice. In 1847 Mr. Ward was elected A.R.A., and in 1855 R.A. He painted several of the frescoes in the corridors of the Houses of Parliament, among them being "The Landing of Charles II.," "The Acquittal of the Seven Bishops," "General Monk declaring for a Free Parliament," and "William and Mary Receiving the Lords and Commons." Among the many other paintings which made his name widely known were the celebrated "Last Sleep of Argyle," "The Execution of Montrose," in 1857-8; "The Emperor of the French Receiving the Order of the Garter" (painted for her Majesty); and "The Night of Rizzio's Murder." Mr. Ward married a granddaughter of the late Mr. James Ward, R.A. This lady is also well known as an artist, and has been since 1850 a frequent exhibitor at the Royal Academy.

To-day we give another drawing from the Exhibition of the Royal Academy last year, and it may be interesting to note that no less than

83 of the works in that collection will be found in our pages from the drawings there exhibited, which were only 140 in number, so that it will be seen that nearly two-thirds of the architectural works exhibited at last year's Royal Academy were published in the BUILDING NEWS.

THE Liverpool Engineering Society held the first meeting of the present year on Wednesday evening; Mr. Morgan E. Yeatman, M.A., President, occupying the chair. The chief business was the reading and discussion of the paper by Mr. J. S. Brodie, on "The Disposal of Town Refuse." The author considered that, in spite of the attention that has been paid to this all-important subject, and the sums of money that have been spent by various companies with greater or less results, the question as to how best to get rid of such refuse as that from dwellings, factories, and slaughter-houses, remains *in statu quo*. Natural water-courses being barred as receptacles for sewage matter, recourse had been had to other methods of disposing of it, and Mr. Brodie considered those that had been tried as (1), precipitation; (2), filtration; (3), irrigation. Under the first head Scott's lime and cement process was described, and a specimen of the cement was exhibited; Whittbread's and the celebrated A B C were also described; Weare's and Bailey Denton's methods of filtration came next. Passing over irrigation as an agricultural question, the author next described the Rochdale tub system and earth closets. In conclusion Mr. Brodie believed that unless something altogether unexpected came forward, towns would have to continue to pay to get rid of their refuse just as they have to pay for their water supply.

It is gratifying to know that the people of Birmingham, true to their reputation, intend at once to restore their Shakespeare Memorial Library which was destroyed by fire last Saturday. The *Echo*, in noticing the fact that while one Shakespeare memorial has disappeared under lamentable circumstances, another is rapidly approaching completion at Stratford-on-Avon, appropriately reminds the authorities of the latter town that it is their duty to accept the offer which has been made to them by Messrs. Merryweather and Co. to provide a hand-engine for use in case of fire in the Henley-street house. Both here and in New-place there are relics of the poet which could never be replaced, and a fire, unless checked at the very outset, would speedily dispose of such well-seasoned dwellings.

CHIPS.

The District Board of Works for St. Saviour's, S.E., have accepted a tender, based on a schedule of prices, from Messrs. Hoare and Son for general sewer and drainage works.

New Sunday school buildings have been opened at Mildmay-park Wesleyan chapel, Stoke Newington. The schoolroom is behind the chapel, and is 77ft. by 30ft.; four class-rooms open into it by folding doors. The architect is Mr. Charles Bell, of London, and the builders are Messrs. Brown and Robinson. The cost has been £1,770.

The Town Council of Bath have appointed a committee to consider the desirability of erecting a public abattoir on the site of the old slaughter-houses in Boatstall-lane.

The Notts county magistrates, at the financial sessions held on Friday, decided to appoint a county surveyor, and appointed a committee to consider and report as to the salary to be attached to the office. From £100 to £500 a year was generally suggested.

The Vestry of Putney have obtained the sanction of the Local Government Board to a proposal to purchase premises at the corner of High-street and Disraeli-road, Putney, at a cost of £2,800, and converting the same into a vestry-hall and offices at a further cost of £700. A committee has since been appointed by the vestry to carry the scheme out.

The King of Portugal contemplates founding a society for the relief of artisans disabled by accidents, and the families of those artisans who have lost their lives by accidents.

A new Board school was opened at Hampstead by Sir C. Reed on Wednesday week. It is of the usual Queen Anne character, and accommodates 240 boys, 240 girls, and 350 infants.

The Bournemouth Improvement Commissioners have appointed Mr. Crickway, of Weymouth, as assistant engineer, to act in conjunction with Mr. C. C. Creeke in carrying out the sewerage works.

Works of water supply are about to be commenced for the local board of Walton, near Preston, under the superintendence of Mr. De Rance, C.E.

The Canterbury Town Council have resolved to request Mr. Rawlinson, C.E., to report—in conjunction with a gentleman acquainted with the agricultural and financial aspects of sewage utilisation—as to the disposal of the sewage of the city.

The Town Council of Hereford have submitted to an action for river pollution brought against them by the Wye Conservators, and acquiesced in an order made upon them to wholly divert the sewage from the river, within three years, by means of a sewage farm two miles east of the city.

Mr. Gordon Reab, who recently resigned the post of borough surveyor of Darlington on being appointed to a similar situation at Preston, was presented last week with a silver tea service by the officials connected with the Darlington Corporation.

A science and art exhibition was opened in the Grammar School, Bedford, on Thursday in last week. It is the first exhibition of the kind in the county, and is pronounced a success.

A stained-glass window has been recently erected at the west end of the parish church of Stoke Holy Cross, Norfolk. The subject is "Moses lifting up the Serpent from the Wilderness," by Messrs. Ward and Hughes, of Frith-street, Soho.

At a meeting of the parishioners of St. Philip's, Heigham, Norwich, held on New Year's Day, it was decided to endeavour to complete the tower and spire of the new church, built about seven years since. The sum required is about £2,000.

CHAPPUIS' PATENTS

FOR

REFLECTING LIGHT.—DAYLIGHT REFLECTORS

OF EVERY DESCRIPTION, ALSO

ARTIFICIAL LIGHT REFLECTORS.

P. E. CHAPPUIS, Patentee.

Factory, 69, Fleet-street, London, E.C.

N.B.—DIAGRAMS AND PROSPECTUSES ON APPLICATION.

The death is announced of M. Auguste Préault, the sculptor, a pupil of David of Angers, who has left many specimens of his talent in the churches, squares, and cemeteries of Paris.

The parish church of St. George, near Monkleigh, Great Torrington, has just had several additions made to it internally, under the supervision of Mr. W. R. Brydon, architect, of Bridgeland-street, Bideford. A parlous screen has been erected between the chancel and Annery aisle, by Mr. Harry Hems, of Exeter.

A new infirmary for the East Ashford Union was opened at Willesborough on Monday. The cost will be about £2,500. Mr. J. Gardner, of Folkestone, was the architect; Messrs. W. and T. Denne, of Upper Walmer, were the builders.

A school-church at Oxford has been opened. The work has been carried out by Mr. J. W. Rowland, of Southampton, from the design and under the superintendence of the architect, Mr. W. H. Mitchell, of Southampton. The room is 36ft. by 24ft.

In our notice last week of the opening of new board schools at St. Augustine's, Norwich, it was stated that Mr. G. E. Hawes, of Norwich, had supplied the boys' and girls' schools with his celebrated "locker deal desks." It should have been "locker deal desks." The desks are of birch not deal.

The whole of the sewers of the Dreadnought Seamen's Hospital, Greenwich, have been ventilated and properly trapped under the superintendence of Mr. Ernest Turner, of Regent-street, upon a plan approved by Mr. Robert Rawlinson, of the Local Government Board.

A new chapel erected by the Primitive Methodists of Wickersley has been opened. The chapel, which will accommodate between 250 and 300 worshippers has been erected by Mr. Henry Flowitt, of Doncaster, from designs which have been prepared by Messrs. Kerridge and Son, architects, of Wisbech, at a cost of about £1,000.

Two houses are about to be added to the Avenue block at the Albert Asylum, Cambridge. Mr. Swau is the contractor.

Works of sewerage are about to be carried out in the town of Halstead, North Essex, from the plans of Mr. J. Bailey Denton, C.E.

Works of sewerage are about to be carried out by the Holywell rural sanitary authority in the townships of Argoed and Bistre. The sewerage will be utilised by irrigation on lands at Spon-green and Nant Mawr, and the total cost of the scheme is estimated at £3,000.

The Wesleyan chapel, in Gold-street, Northampton, was reopened on Tuesday week after alterations from the designs of Mr. Newman, including the addition of an apse, domed, panelled and gilt, 24ft. deep, and containing choir stalls, and the substitution of pitch-pine seats for pews. The outlay has been £2,000. Mr. T. Cosford, of Northampton, was the builder.

A new cemetery was consecrated by the Bishop of Lichfield on Wednesday week at Brimington, near Chesterfield. The area is two acres, but five acres more can be brought into use. There are chapels for Episcopalians and Dissenters, connected together and surmounted by a turret. There is also a sexton's house. The total cost has been £4,500. Mr. Rawlinson, of Chesterfield, is the architect.

A sewerage scheme is to be prepared for Barton-under-Needwood by Mr. Walker, of Cannock, for the Barton-on-Trent rural sanitary authority.

A new reredos has been placed in the chancel of St. Mark's Church, Lincoln. It has been constructed from the designs of the Rev. F. Satten, of Brant Broughton.

The Bridlington Local Board have applied to the Local Government Board for permission to borrow the sum of £5,000 for carrying out works of sea defences on the North Cliff from Sand-cut to Sands-lane from the designs of Messrs. Clarke and Picknell, of Hull, to whom the first premium was awarded in the recent competition.

The Town Council of Inverness have resolved to apply for a provisional order for an extension of their borrowing powers under the Water and Gas Act, to the extent of £20,000 for water, and £15,000 for gas.

A contagious diseases hospital has been erected for the Eastbourne rural sanitary authority. Mr. G. A. Wallis was the architect, and Mr. Cornwall the contractor.

At the recent annual distribution of prizes and certificates at the Dundee School of Art Mr. D. S. Grubb, recently art master at Dundee, and now of Elgin, was presented with an inlaid walnut davenport as a token of the appreciation of his labours in Dundee.

The will of Mr. Frederick Pepps Cockerell, of 18, Manchester-square, late honorary secretary of the Royal Institute of British Architects, has been proved under £14,000 personality, and that of Sir Francis Grant, P.R.A., under £20,000.

The parish church of Ringshall, West Suffolk, was reopened on Wednesday, after restoration, from the designs of Mr. R. M. Phipson, of Ipswich and Norwich. Mr. R. Tooley, of Bury St. Edmund's, was the contractor. The outlay has been about £1,000.

Mr. Steed is commissioned to execute a monument of the late Princess Alice, Grand Duchess of Hesse-Darmstadt, which is to be set up in Whiphogham Church, Isle of Wight.

HELLIWELL'S Patented NEW SYSTEM OF AIR & WATER-TIGHT IMPERISHABLE GLAZING.

All Woodwork is covered, and no outside Painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

"It is suitable for Railway Stations, Mills, Weaving Sheds, &c., but is specially applicable to Conservatories, Plant Houses, and Orchard Houses, and we should be very much inclined to try the system. It is certainly worth looking to."—*Builder*.

"And will, in our opinion, supersede any other similar system before the public."—*BUILDING NEWS*.

"It seems to meet the end in view more nearly than anything we have seen yet."—*The Field*.

"The patent has given high satisfaction to every one using it."—*The Christian Union*.

"Convincingly prove the new Glazing System to be worthy the attention of readers of the 'Keytone.'"—*The Acetylene*.

For Estimates, Drawings, or Particulars, apply to the Patentee, T. W. HELLIWELL, Brighouse, Yorkshire; or, 19, Parliament-street, London.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Institution of Surveyors. Discussion on papers by J. F. Hedley, on "Rating of Railways," and "Terminal Charges," 8 p.m.

"Society of Arts. Center Lecture No. V., on "Mathematical Instruments," by W. Matthew Williams; 8 p.m.

WEDNESDAY.—Society of Arts. Paper: "The Modern Science of Economics," by H. D. Macleod; 8 p.m.

THURSDAY.—Society for the Fine Arts, first conversazione.

WHITLAND ABBEY GREEN SLATES

These SLATES are of a grey-green tint, are stout, and made in all sizes. A large stock available for immediate delivery. For further particulars (with a list of important buildings covered) apply to the MANAGER, Clynderwen, R.S.O., Carmarthenshire.—[ADVT.]

Trade News.

WAGES MOVEMENT.

MERTHYR.—In consequence of depression in trade the Merthyr builders have resolved to enforce a reduction in wages of 10 per cent.

AVR.—The proposed reduction of masons' wages by 4d. per hour dates from Monday last. The men, however, have intimated that they will resist the change.

SHEFFIELD.—The whole of the carpenters and joiners of Sheffield have received notice of a reduction of 1d. per hour, and after the 24th of June will be required to work four hours longer for a working week than at present. They have hitherto been getting 8 1/2d. per hour, and working 49 1/2 hours per week; but the masters have now issued notices of reduction to 7 1/2d. per hour, and also of an extension to 53 1/2 hours per week. The new rules, of which these proposed alterations form a part, contain several other proposals which are in great disfavour with the men, who intend to hold an aggregate meeting to protest against the action of the masters.

BANBURY.—The strike in the building trade at Banbury has terminated, the men having accepted the reduction of 1d. per hour.

BUXTON.—The differences between the builders and their workmen have been agreeably adjusted.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.
Agent: Mr. E. CRICKMATT, 4, Agar-street, London, W.

TENDERS.

CHELSEA.—For works required in Pitching Clabon Mews, on the Cadogan and Hans-place Estate. Mr. W. Forbes F. Ashdown, surveyor:—

Mowlem and Co. (accepted) ... £742 10 0

DAREMTH.—For the erection of a mistress's residence and additions to school for the School Board for Darenth, under the superintendence of Mr. Wm. Eve, IO, Union-court, Old Broad-street:—

Blake £743

Page 670

Walter 656

Hill 590

Gumbrell 487

*Accepted subject to approval of the Education Department.

EDMONTON.—For hot and cold water pipes and fittings in the workhouse laundry, for the Edmonton Board of Guardians:—

Bushy and Co. £66 12 0

THE BUILDING NEWS.

LONDON, FRIDAY, JANUARY 24, 1878.

POLYCHROME ORNAMENTS.

THE great illustration displayed at the Paris Exhibition of decoration in every form, and under every aspect, have brought anew into the field the genius of M. Racinet, who may be regarded as being for France the leading master in this art. He has assembled around him, indeed, a school, at the latest works of which a glance at the present time may be useful, chiefly as they apply, however, to discoveries in archaeology, and adaptations to architecture. It is a French style, be it remembered, and one belonging to the third quarter of the nineteenth century, which we are describing rather than criticising; and it may be looked upon as the artistic outcome—considered from one particular point of view—of the Christian year 1878, with all its rivalries. The chromo-lithography, in fact, of the Universal Exhibition was largely illustrative of architectural ideas—Grecian, Roman, and Mediæval—but all preponderating towards what is supposed in certain quarters to be the modern taste. Yet it is altogether unnecessary, for the sake of interpreting these latest developments, announced in the preliminary reports of the Paris Exhibition Commissioners, to do more than traverse the ground selected by the Commissioners. They say: “we have two thousand suggestions to consider—we have a hundred coloured plates to compare, and we have, moreover, the claims of architects, sculptors, painters, decorators, furniture-makers, stuff and paper colourers, carpet-weavers, cabinet-manufacturers, jewellers, and toy-makers to consider.” In the midst of all these, and above them all, arises from the French Exhibition of 1878, with its judgments completed, the question of Polychrome Ornament. The folio, quarto, and octavo volumes already published assist us in arriving at a result. They do not, however, confine themselves to examples of the present; they embrace—and in them the highest and brightest lessons are included—the polychrome architecture and ornament, both especially and variously of Greece, India, China, Japan, Persia, Pompeii, Egypt, and Assyria, though the illustrations are fewer or more numerous, exactly as the nationalities and their historical monuments vary. Thus of the Pompeian relics, it is said, they have been, in their meaning, expanded too far—they have been carried beyond and worked too far from their legitimate significance; but this is not the question just now. We are reviewing at once the earliest and the latest efforts and experiments of the ancients in polychromatic decoration, whether applied to architecture or otherwise, and the revival of M. Racinet with his academy appears to afford an occasion. The original work, of course, is well known. Its successors in several, and especially in the latest editions, are not. They complete, however, the epitome of French historical and contemporary taste in these respects, and are, therefore, worth studying. From the first illustration, styled “Primitive,” to the last or hundredth styled Eighteenth Century, twenty titles of ages are employed, leaving out those senseless distinctions of time and manners, which are supposed to be marked by the reigns of particular kings. Then—now that M. Racinet and his coadjutors—now that their labours are unfettered, and now, indeed, that they have been stimulated by the emulations of the past year—what do they undertake to say? To begin with, they have, upon the whole, repudiated their former editions, not less than their former tradi-

tions, and would begin the race anew. They commence by disavowing in great part obedience to mythical laws “and superior ideas” with which they refuse to conform. They even complain that painting and sculpture are “more or less fettered by sense and logic.” They admit, as a confession, that architecture must comply with various conditions—“solidity, the purpose of the building, and the co-relation of exterior aspect with interior use;” but they add, which is their object, “ornament, and especially that kind which now occupies us—the decoration of coloured surfaces—has a sphere of action doubtless more modest, but yet enjoying much greater liberty.” And so these authors go on, colour pencil in hand, building and painting up, from complicated interlacings, capricious arabesques, chemical compositions, in which the line, the flower, the animal, and the human figure are blended. It is with the tinting rather than with the outlines of the art thus illustrated that the preliminary exhibition reports are concerned. Gathering the experience of the entire world, as illustrated at Paris, the results are interesting, although in a degree monotonous.

Under the head “Primitive Decoration” we have, apart from carved forms and outlined patterns, a very limited use of colour, confined often to a deep black, contrasted with a bright red ground. The Mexican types suggest a larger abundance and barbarism of colour, but these have little to do, even in this connection, with historical art. So may be passed by the Egyptian and Assyrian, the Greek, Etruscan, and Greco-Roman periods, except that colour was employed in them all with a luxury of lavishness which, so far from being art, was wasted upon the horns of a bull with scarcely less contempt than was exhibited towards the altars of a temple. In the decorative painting of dwelling-houses the Romans, no doubt, took everything from the Greeks and the Latins generally, whether it were in Pompeii or in Herculæum, though in the former the purest instances are found. In it we find, moreover, the noblest applications of polychromatic colouring to mosaic, though this latter branch of art underwent, in the hands of the Romans, from the times of the Empire, many important modifications. They brought it, indeed—and here was the ruin of the art—into rivalry with the highest forms of painting. The Greeks had made the compartments of their paved floors represent ornaments, branches, scrolls, festoons, interlacings, and, passing onwards from these fanciful forms, to somewhat in the nature of arabesques, significant symbols and attributes, griffins, chimæra, tragic or comic masks, the signs of the zodiac, vine branches, birds pecking at fruits, and all the other well-known motives of classic and pagan ornamentation. But whence the colour? Pebbles, stones, natural or tinted marbles, paste and terra cotta, shells and fragments of pots, no longer enabled to contend with the true richness of painting, came in at a time when painters, impelled, says M. Jeançon, by a mad love of brilliancy and richness, borrowed from red lead, purple, azure, gold, and silver, their striking glitter and deceptive contrasts, mosaic demanding fresh resources from a multitude of precious stones, such as were employed in adorning St. Mark at Venice, and St. Sophia at Constantinople—agate, jasper, cornelian, sardonyx, emerald, turquoise, lapis-lazuli, “to imitate every fancy of the painter with his seven or eight principal colours.” This fashion, however, was rather a deceptive than a real one. The worker in mosaic had, it is true, more shades at his service, and the painter fewer tints; but his productions after all were more costly, although more glittering to the eye and smoother to

the touch. As a polychromatic art it, in the common course of things, had to give way, and become little more than a mere manufacture; the painters regained their position, and with their restoration arose a fresh period in the semi-barbaric architecture which condescended, in part, to colouring for its splendour. Such is a part of the parable read by M. Racinet and his brethren to their contemporaries; and since two-thirds of artistic France accept—though not without criticism—these conclusions from artistic history, they may be worth while considering.

The magnificent illustrations of the work explain their meaning. They abide by a theory that the ancients possessed a perfect knowledge of colour, and of its mutual relations. This is our key and clue through the whole labyrinth of the hundred splendid plates before us, re-arranged and re-adjusted, so to speak, as graduations in the history of the art—the blue ground in imitation of the sky, everywhere of the same intensity, with, however, the upper part predominating, and the lower appearing more distant and light, producing that aerial look which, on the part of the Greeks, was the result of practised, though imperfect, reasoning, while, in modern physics, it constitutes a theory of advancing and retreating colours. Without following the authors through all their details, we may quote them where they say, “When looking from a certain distance at coloured windows formed by red and blue squares, surrounded by a black grating, it seems as if the red were more prominent than the blue, and were actually standing out;” and “what completes the value of this mural painting is that theory further demonstrates that an artificial light of wax and oil, far from weakening the effect, only renders it more powerful.” The examples of the East, including China and Japan, are cited by M. Racinet and his colleagues, mainly to the effect that in art all isolated civilisations are unprogressive; but they add, “the symbolism of colours, enunciated by the Chinese ‘rites,’ is in reality nothing less than a statement of the early primitive colours recognised by painters”—yellow, red, and undecomposable blue. The Indian, Arabian, Moorish, and Persian annals exhibit in these respects similar results. The colours of their art are rich and yet monotonous; they begin with plenitude, and make no progress, but the Moorish decoration, as M. Racinet elaborately shows, is distinguished by a generally-adopted system, based on the principal employment of the three primary undecomposable colours—blue, red, and yellow—represented by gold. But in the Persian carpets of the most famous and luxurious eras we find shadings and tints in every direction—as scales rising from the ground, black slightly tinted white, blue, red, yellow, and what artists have agreed to call flesh colour, with a proper employment of gold, modified by a “judicious play of light on the paler parts.” The following passage is of exceeding interest:—“In the parti-coloured grounds, passing from black to white, from red to green, changing colour with the design, the Indians succeed in neutralising the most glaring intensities into a general harmony, by means of which gold, thrown over the rawness of the colours, seems to unite and warm, and, as it were, blend them into one, like a transparent veil interwoven with the gold itself.” These are studies, in the art of coloured decorations, which may be carried farther than even the speculations of M. Racinet, who goes on with the adornments of old German cathedrals, Byzantine altars, and even Scandinavian church-work, always in search of colours and their use. He finds it difficult to separate the history of design in outline, from that of colour-

ing in patterns, and thus occasionally confuses the two; but the difficulty was not an unnatural one, since the second form of idealism so irresistibly sprang from the first. In fact, no known writer has ever succeeded in separating the two completely. There are three processes in the production of ornament. It is laid down: the drawing or design, the colouring, and the relief. By the help of these means the artist may obtain the most varied results, all coming, however, within the following categories: The invention of subjects, purely imaginary, and foreign to the productions of Nature; the conventional representation of natural objects, expressed merely in their essential characteristics, and under a generalised type; and the imitative representation of objects, in which Nature is followed, both as regards design and colouring. This last topic is the most important to us at present. The frequent use of purely imitative painting, as M. Racinet admits, suggested charming decorations to the magic artists who adorned modern taste, and especially that of France, in the seventeenth and eighteenth centuries; not altogether, however, without abuse, not less than injury, to certain industrial arts—ceramics, painting on glass, and the manufacture of carpets. For example, “which would have gained by keeping to, and might even now gain by returning to, more truly decorative processes?” But, as a theorist has his right to the last word, we may allow M. Racinet his liberty of saying—“Where the representation of objects is ideal or conventional, the colour is likewise conventional, and the ornamentalist remains master of his palette. The severity of the design is thus redeemed by liberty in chromatics and the advantage of being able to choose and arrange the colours at will, without any necessity for resemblance, or even probability.” This was the original lesson, taught in Asia, and it has never, for art purposes, been effectually untaught in Europe.

ARCHITECTURAL GEOLOGY.—I.

IN olden times, when there was comparatively but little intercourse or traffic between different parts of the country, owing to the absence of good roads and the difficulty and expense of conveying materials over any considerable distance, the geology of each district exercised a far greater influence upon the character of its architecture than it does at the present day, when good roads, canals, and railways have made the carriage of building materials so easy and inexpensive. Thus we find that in those districts where stone of any kind could be obtained by digging down a few feet below the surface or from neighbouring quarries, hardly any other than the local stone was employed in old buildings, except perhaps where it was not of sufficiently good quality for carving or dressings, in which case a better stone would be brought from a distance, when the cost of the building was not an object for consideration. In some districts the only stones found near at hand were the rough flints, which are plentiful in the chalk and in gravel beds; and yet with this unpromising material some of the most beautiful architectural effects have been produced. In other parts, where no stone of any kind was to be procured, but good beds of clay or brick-earth abounded, much picturesqueness was obtained by the artistical use of brick, which was cut and moulded into different forms, so that the buildings in those localities often rivalled in beauty those erected in others which were favoured with a supply of good building stone. And even where none of these materials were at hand, but only sand or gravel could be obtained, our ancestors were never at a loss for materials, for by a judicious use of the timber which

was then everywhere plentiful, and by mixing lime with their sand, they produced those tasteful and substantial dwellings known as half-timbered houses, which equal in comfort and durability many of those built with stone or brick.

In the present day, however, all this has been greatly changed by the constant and rapid intercourse and traffic between all parts of the country, by which we are enabled, in many cases, to bring building materials from a distance at as low a price as we can obtain an inferior article which abounds in our neighbourhood, so that we have, in fact, the choice of a large number of building materials, and can select those which best suit our design. Still, however, it will always be found that local material stands its ground for the majority of buildings, especially in those erected as dwellings for the middle and lower classes, which afford but little scope for architectural display. Thus, in a clay country, these buildings will always have brick for their walls, while in a stone district the cottages as well as the mansions will be built of stone, to the almost entire exclusion of brick. In places where sand and gravel are plentiful they may be economically employed for walling by an admixture with a small proportion of lime or cement, thereby producing a concrete which will rival stone or brick in strength and durability.

We therefore, propose, in this and subsequent articles, to examine the peculiarities of the successive geological strata, and to consider what resources for building purposes each of them contains, so that the architect who is about to erect a building in any particular district may be able to ascertain beforehand what kind of walling material he is likely to find to his hand, and to arrange his design in accordance with his material. Thus in one locality he will find an excellent building stone, and in another a very inferior one, while in other places he can obtain excellent bricks and no stone, except what is brought from distant quarries; or the locality may be devoid both of brick and stone, and his only available material either sand or gravel.

Tertiary Strata.—The most recent geological deposits generally consist of sands and gravel which have been worn away from the older rocks by water, and transported to their present position, some of the pebbles having been brought from a great distance and rolled quite round by friction against each other in the course of their journey. In some places these deposits are of marine origin, being raised sea-beaches, consisting of sand and shingle which have attained their present level by upheaval of the land or the retirement of the sea. Such deposits are always valuable to the builder for making concrete and mortar; they are found in many parts of the Devon and Cornwall coasts, from Torquay to Mount's Bay and round to Bideford Bay; at Weston-super-Mare and the Mumbles, near Swansea; while on the Dorset coast we have the Chesil Beach, 15 miles in length and 200 yards in width. Further inland are the Burtle beds of the Somerset moorlands, which are sea-beaches consisting of red marl with sand and shells.

The alluvial deposits of gravel and sand are those which are most frequently met with in all parts of the country, having been produced by rivers, lakes, and estuaries; they often contain valuable beds of clay and brick-earth, alternating with the gravel and sand. One of the most extensive tracts of alluvium is that of Holderness, in East Yorkshire, extending also down the eastern part of Lincolnshire as far as the Fens of Cambridge; another tract is found stretching along the Lancashire coast from Fleetwood to Seaforth, near Liverpool. An alluvial deposit extends along the Bristol Channel from Chepstow to Cardiff on one

side, and on the other from Berkeley to Portishead, spreading out near Clevedon, Weston, Glastonbury, Bridgewater, and Ilchester. From the sand found at Bridge-water are made the “Bath bricks.” The alluvial deposit forming Romney Marsh, in Kent, is below the level of high spring tides. That deposited near Maidstone, in the faults of the Kentish rag, affords an excellent clay for brick-making. Near the mouth of the Thames is a large tract of alluvium, as at Sheppey, Shoeburyness, Foulness, and at Clacton-on-Sea, where there is a thick gravel bed with laminated clay. In many parts of the Thames Valley we find beds of brick-earth from 5ft. to 30ft. in thickness, as at Wanstead, Tottenham, West Drayton, Ilford, and Erith; while in the valley of the Medway extensive deposits of gravel are found. The eastern part of Norfolk is covered with thick alluvial deposits of sand and gravel.

The term “drift” has been applied to beds of gravel, sand, and brick-earth, which have been deposited during the “glacial” period by the transporting power of ice during a long prevalence of Arctic cold. The beds of gravel on which a large portion of London is built have been deposited in this manner, as well as many others found in the Thames Valley about Ilford and Grays Thurrock, in Essex; Richmond Park and Wimbledon Common, in Surrey; and at Wellhill, in Kent, where it lies upon the chalk. Drift beds of gravel cap the London clay at Stanmore, Barnet, Totteridge, Muswell Hill, Highbury, Epping, and Shooter's Hill. At Chelmsford the glacial deposit takes the form of brick-earth, while in some parts of Norfolk, Suffolk, and Essex, we find beds of clay full of chalk, pebbles, and flints, as at Tivetshall, Eye, Framlingham, Halstead, Dunmow, and Braintree, as well as at Watford, Biggleswade, Huntingdon, and Horncastle. Near Hertford is a drift deposit of gravel, consisting of chalk, flints, and quartz pebbles, with sand and seams of chalky boulder clay. In some cases, as at Norwich, the glacial sand has been converted into a building stone through the dissolution of chalk by carbonated water, which has percolated the mass and acted as a cement to hold the particles of sand together.

The “London clay” series of beds are next in order of age to the drift, and consist of marine deposits of stiff clay, with occasional beds of sand. It is found most extensively under and around London, along the Valley of the Thames, and immediately overlying the chalk. There is also another large deposit of the same series called the Hampshire basin, extending along the western part of Sussex, South Hampshire, into Dorset as far as Dorchester and running inland to within a short distance of Salisbury. In some places a deposit of sand called the Bagshot beds is found overlying the clay, as at Bagshot Heath, Windsor, Chertsey, Sandhurst, Weybridge, and Esher; also on the higher grounds around London, at Harrow, Hampstead, and Highgate. These beds are chiefly sand, of great value for building purposes, but also contain occasional layers of brick-earth. In the Isle of Wight the Bagshot beds attain a thickness of 200ft., and consist of fine, pure white sand, highly prized for glass-making; while at Poole, in Dorset, they contain a bed of clay, which is used for making ornamental tiles.

The average thickness of the London clay beds is about 400ft., but in some places in and around London it has been bored through and the chalk reached 150ft. below the surface. In the London basin this deposit is found on the south at Epsom, Croydon, and Beckenham; also at Ditton, Sutton, and Merton, in Surrey, there are uncovered tracts of clay. It extends westward, as far as Windsor, and by the banks

of the river Colne to Uxbridge and Hendon. All the elevated parts about Norwood and Sydenham, Forest Hill, Shooter's Hill, Stanmore Heath, and Richmond Park, are formed of London clay, and it extends along the left valley of the Lea from Waltham Abbey to Chingford in a range of clay hills. Wherever it occurs near the surface it is extensively used for making bricks and tiles. Some blocks of an argillaceous limestone called "Septaria" are frequently found embedded in the clay, and are used for the manufacture of Roman cement, being obtained from the cliff of London clay at Sheppey, and also by dredging, near the mouth of the Thames.

Below the beds of the London clay is sometimes found a stratum of *Plastic clay* with sand, which is developed near Woolwich, Reading, and at Allum Bay and Whitecliff, in the Isle of Wight, as well as on the Dorset coast, at Studland Bay. It is used for making bricks and the coarser kinds of pottery.

No spring water can be obtained by sinking wells into the London clay, on account of its impervious nature, and it is necessary to bore through to the chalk or greensand below, from which an abundant supply is generally obtained; this water, however, has a considerable degree of "hardness," from holding in solution the bicarbonate of lime; but if lime-water is added to it an insoluble carbonate of lime is formed, which falls to the bottom, and nearly all the lime in the water is thus got rid of.

TOWN AND COUNTRY MANSIONS AND SUBURBAN HOUSES.*

OF late years there has been a more than plentiful supply of illustrated designs, yet some architects are so prolific that a volume of designs every now and then appears, for which the only apology for publication seems to be that they are illustrations of executed works. Examples of buildings which are really erected have their value, but it is in proportion to the merits of the works or the typical character or speciality of the buildings themselves. New designs for houses, to be of any use, should be suggestive of planning, or they are of little value either to the architect or the public, and the most they can profess to show is some typical and special arrangements that may be carried out. Mr. William Young has added another contribution to the literature of stock designs, and he says in his preface the success which has attended a previous work illustrative of suggestive designs "has induced him to publish a supplementary volume of a more practical character, with illustrations of executed buildings." The work before us professes to illustrate recent improvements in the planning and construction of domestic buildings, and to give some information on sanitary and artistic details. How far these objects have been attained in Mr. Young's present work we leave the reader himself to judge, but we may ask one question that pertains equally to other works of this kind, and that is: For whom is the work specially intended—the professional man or the public? Upon this question much of the value of the work rests. If the author intends his work for the unprofessional reader, there is much in it that will be of interest, and some useful information may be acquired respecting the wants of houses; and we believe, from a general perusal, that this has been the author's intention, though we rather think some irrelevant topics have been introduced into the introductory pages. The chapters on architectural design from

Gothic to Queen Anne, Gothic *versus* Classic, seem to us rather out of place in a book of designs, however much in place it might have been in a work treating of style or architectural æsthetics.

Mr. Young gives some good—if not new—advice to the builder of houses. The advantages of well-planned, well-designed houses are dwelt upon, though we cannot admit that modern architects are so keenly alive to the importance of scientific scheme and construction in house-building as Mr. Young seems to believe; nor can we endorse the opinion that there is more real life in architecture, and more fertility and vigour of the inventive faculties of design at the present day than at any former time. The author in the next paragraph qualifies this considerably, for he truly says, "If anything we are too prolific in design," we run riot in the display of this faculty, and bring too much grist to the mill, and he concludes by saying we have so much food, both artistic and scientific for the brain, that it would be a blessing if invention would stop for a time to allow of digestion—a remark which entirely accords with our opening observations.

We skip over the chapters on style which give some sensible advice about selecting a style, and the motives that should dictate the adoption of Queen Anne or any other fashion, simply noting a strong *pencilant* for eclecticism on the part of the author, also some remarks on plans and arrangements of houses, in which we find ourselves at one with the author in preferring kitchen offices placed on the ground floor. In the chapters on the various apartments and sanitary details some useful observations will be found, but we pass on to notice the manner in which the author's principles are put into shape. Many of the designs are old faces to us, and we recognise some that have been illustrated in our own pages. Plans, elevations, and perspectives are given, and the author acknowledges the assistance he has received from Messrs. M. B. Adams and E. W. Poley in preparing some of the plates for photo-lithography. Mansions in Cadogan-square form the subject of the first plate, and these we glanced at last week in our notice of new works at Chelsea. Mr. Young has here adopted rather the features of the Renaissance, more regular than those of the Queen Anne, followed by other architects in the neighbourhood. There is little to find fault with, though we may take exception to the chimneys, and some of the lesser features, and on the whole a little less redundant treatment in the decoration and more repose would have been better. If the centre bays had been omitted a quieter and more agreeable effect would have been obtained. By the bye, we notice the plans of the centre houses do not quite agree with the elevation, as the bays have only two windows in plan, while they extend the whole width of front in the façade. The plans are the best part of the design, and we see the author has lighted his staircase, which forms a central square hall between the back and front rooms, by a skylight. A gallery communication is also shown between the front and back rooms of the ground and first floors; and this gallery forms one side of the staircase area, and is lighted from it. The library and dining-room on the ground floor, and the two drawing-rooms above, are thus connected privately—a feature we have before recommended. A boudoir is placed at the end of the back drawing-room, though it does not fully occupy the width of the plot, but is lighted from a narrow side area, not perhaps in the most desirable way. A conservatory, however, outside the back drawing-room window, and having access from the boudoir, is a redeeming feature. On the upper three floors seven

large bedrooms, besides three smaller ones and dressing-rooms, are obtained. A lift traverses the house near the kitchen, and a stable and coachman's house occupies the rear of the plot. The next design illustrates a pretentious manor-house, erected at Haseley, in Warwickshire. Here, again, the plan has most to recommend it; for the *porte-cochère* and the tower behind it combine somewhat incongruously with the composition—while the number of breaks and projections, and the multiform shapes of bays and angle oriels, confuse and produce a frittered effect. The garden front makes by far the most successful composition. Looking at the plan, we fail to note a compass-point, which—as in this and other plans—would have much added to the value of the examples. The outer hall, inner hall, staircase, and billiard-room arrangement is good, and the inner communications are better than in many houses of this class. Chelsea House, erected from designs of the author for Earl Cadogan, is a costly example of Italian, executed with ashlar facings of Portland stone. There are some points, such as the fragments of pilasters at the angles of the bayed projections, amenable to criticism; but the plans are skilfully contrived for the site, and afford a good example of town planning. The chief apartments are said to be decorated in different styles. The dining-room is after Adams, the library Queen Anne, and the drawing-rooms Louis XIV. and XV. We cannot admire some of the latter work—it is tawdry and overloaded, especially in the frieze panels. The dining-room decorations (Plate IX.) and the ceiling (Plate XII.) are in a more refined taste. The effect of the decoration of Chevening Hall (Plate XXX.) is perfectly spoilt by the over-liness of the drawing. Plate XIII. shows the view of principal staircase, in which there is much that is good, though the lower Ionic columns look out of proportion in drawing. Holmewood House, Hunts (not Hants, as spelt), in red brick and stone, is pleasing in elevation, though somewhat heavy in detail. We do not like the prospect tower—a treatment the author seems partial to—and the details of entrance look somewhat coarse. Plate XV., showing staircase, exhibits one or two faulty features: we allude to the running in of the lower arcade cornice upon the return landing, and the prodigious cove of ceiling, the end of which does not terminate at all happily against the window. In this and other illustrations there is a coarseness in the shading which detracts from the effect. Plate XVII. shows a design for a mansion at Kensington. The front façade is light and freely treated in a sort of Renaissance suitable for red brick, but the porches are not so happy. The arrangement of hall and staircase is clever. In the design for house at Broadwater in half-timbered style there is a lack of connection, and the centre gable treatment has a rather hodge-podge effect, intensified by the porch not being centrally placed. The plans are much better. Oxhey Grange, Herts, is a remodelled shooting-box, and is an example probably of little value. The porch placed askew, the diversities of gable treatment, and the heavy splay to the windows of the near gable are not models to follow, however well they may have served their purpose. The house at Castle Hill is a better example of a small country or suburban house, with sunk kitchen offices. Some gate lodges and a few other designs, including studies for chimney pieces, are illustrated. Though there is nothing very objectionable in any of the designs, there is, to our minds, a rather over-laboured effect in some of them, which has been perhaps intensified by the style of drawing and lithography. There is a flatness and deadness of shading in many of

* Town and Country Mansions and Suburban Houses: with Notes on Sanitary and Artistic Construction. Illustrated by 30 plates. By WILLIAM YOUNG, Architect, London. E. and F. N. Spon, Charing-cross.

the illustrations, and we are of opinion that a more sketchy style would have been better adopted; otherwise the work is well printed and got up, and will take its place creditably among works of a like nature.

DANGEROUS SEWERS AND HOUSE DRAINS.*

DR. W. COPLEY WOODHEAD, of Leeds, has published a pamphlet under the above title, the object of which is to set forth a new mode of preventing the entrance of sewer gases into houses. Our readers have had so many inventions brought under their notice of late that any new scheme may appear superfluous. Dr. Woodhead discusses some of these, and he attempts to show that they are not only useless, but often a source of danger. Referring to a special contrivance much advocated of late, in which there is an air-chamber with grated opening, into which the house pipes enter, divided by a partition in the centre, and a siphon trap on the sewer side, it is argued that the gases will be drawn into the house—the heavier gases especially—because they will not rise so readily out of the chamber as the lighter ones. It is also contended the greater weight of the external air in the air-chamber will force up the sewer gas, and any specific germs, into the house, via the house pipes. The ordinary plan of carrying up to the eaves the soil-pipe as a ventilator is for a similar reason pronounced inoperative as far as the entrance into the house of specific germ poisons generated in the drains. Dr. Vacher is quoted to show that by keeping out sewer gas we do not prevent the entrance of the small albuminoid particle, insoluble in water, which is the specific germ of typhoid, and is propagated in sewers and pipes. Sulphuretted hydrogen might be shut out, but still the poisonous particle may elude the checks. It is doubtless a great error to imagine, as many do, that anything we can smell is dangerous. What is dangerous is not a gas at all, and could not, like gas, be volatilised. Speaking of Mr. Norman Shaw's plan, Dr. Woodhead does not consider it excludes sewer gas, as an experiment he describes proved that water placed in the soil pipe became impregnated with fungi of the same character as that in the siphon trap. Proceeding to explain his own plan, the author says, "The principle for which I contend in preventing sewer gas and specific germ poisons contaminating the atmosphere in the dwelling under our existing mode of constructing sewers consists—first, in having a free and constant circulation of fresh air through the house drain from its commencement to its termination in the main sewer, the current always setting in the direction from the house to the sewer; secondly, in placing an effectual barrier to the entrance of sewer gas or specific germs out of the sewer into the house drain." Dr. Woodhead, to attain his object, makes the aggregate area of the openings that admit the fresh air larger than the aggregate area of openings for the efflux of that which has become vitiated. By this means the outward and heavier air overbalances the lighter gases contained in the drains, and they escape upwards. To accomplish this the author inserts into the house drain a funnel-shaped mouthpiece for ingress of fresh air, into which the soil pipes discharge at surface, open to the air by a grating, and another and smaller outlet-pipe or egress-tube at a short distance from termination of drain, or at junction with the street or main sewer. Both openings terminate at ground level. The house drain and the two openings thus

form a connected and bent tube, through which a circulation of air takes place from the larger or house end to the smaller or sewer end of drain. A siphon is also placed to check the sewer gas from entering this drain between the main sewer and the egress tube. The theory is that a larger and heavier column of air at the mouth of house drain will overbalance and force out at the egress tube any lighter gases generated in the intermediate length of drain. In most of the systems the air is made to enter at the foot of soil-pipe, the current being through the house-trap and upwards. In the plan under notice the current through drain is reversed, and is made to clear the drain outward from the house. The heavier gases are also driven out of the egress tube by the passage of sewage through the drain, the vacuum being filled by a current of fresh air from the larger opening, and by this means it is thought any specific germs in the drain will be destroyed. Further to check the entrance of sewer gas or germs into the house drain, another siphon is placed at the junction of sewer and drain, and a manhole or air-shaft is built to the ground level, where a grating is placed, up which any gas or germ poison that escapes the first trap finds vent. The other diagrams in Dr. Woodhead's pamphlet show different forms of the same system; one shows a double ventilated siphon trap near the house, for cases where the larger scheme cannot be carried out. We cannot see the absolute utility of this double siphon if the open receiver is introduced into the head of the drain, as this opening and one air-tube on the house side of the trap would create the necessary current. This second pipe and siphon appear moreover to us to complicate the system, which is based on a correct principle. We can recommend Dr. Woodhead's pamphlet to all sanitary engineers. The explanations are, however, somewhat diffuse and discursive, and the principle might have been explained in less than half the space.

ARCHITECTURAL ASSOCIATION.

A MEETING of the Architectural Association was held on Friday evening; the President (Mr. H. L. Florence) in the chair. The following were elected by show of hands as members:—Valentine Vagolini, W. M. H. Burditt, B. L. Westbrook, J. S. Blake, H. Moore Newlyn, D. J. Budge, H. Ough, A. Ebb, H. G. S. Young, Lewis Edwards, J. G. Hall, A.R.I.B.A., M.I.S., A. W. Bowen, Reginald Beesley, W. H. Bendle, G. S. Weir Tappen, Brett A. Elphicke, J. B. Chubb, T. E. Jamieson. Mr. PAGE (Hon. Sec.), announced that the first visit of the session would take place on the 25th inst. (to-morrow), and would be made to the Grand Hotel, Northumberland-avenue.

MR. THOMAS BLASHILL read the following paper on

PARTY WALLS: THE LAW AND THE PRACTICE.

There exists in London a long-established custom of building between adjoining houses not two separate external walls, one standing upon the ground of each owner, but one wall, the centre of which is usually placed perpendicularly over the boundary line of the two properties, which wall is known as a "party wall." The obvious convenience of this arrangement, both as saving space and reducing the cost of building, has caused it to become general in places where land is valuable. It is therefore of importance that those who have to deal with such property should be acquainted with the laws relating to it, and with the difficulties most likely to be met with in the course of practice. Although the subject is not very simple, I hope to submit it in a shape that will lead to useful discussion. In London the law with respect to party structures is contained in the Metropolitan Building Act, 1855, the provisions of which have been embodied in the local acts of some other towns. To this Act I shall limit the subject, for where it is not in operation the

rights and duties of parties who are presumed to be tenants in common of a party wall are not so much matters of general interest and importance as is the case where such walls are the usual mode of separating buildings from each other. What is a party wall? The Act says, in the interpretation clause, "party wall" shall apply to every wall used or built in order to be used as a separation of any building from any other building with a view to the same being occupied by different persons." This is generally satisfactory, and a wall standing as the separation between the rooms of two houses may almost safely be considered a party wall. But there are cases in which, on examining the construction and the elevations of two houses, A and B, it is clear that A was first built, as a distinct and complete house, and that B has afterwards been added, the wall in question having been made use of, perhaps, surreptitiously, and the deeds relating to A may show that the ground on which the whole wall stands was conveyed to the owner of it. I think that when this is clearly seen the wall must be considered to be the external wall of the house, A. The wall was certainly never built in order to be used as a separation of the two buildings, and the true boundary line of A seems to be at the outer face of the wall, while the house, B, was wrongfully built without any external wall on that side. Although many persons differ from this view, I think that as the land on which the wall stands is wholly the property of the owner of A, the most that can be said is that the owner of B has acquired an easement over the wall to the extent to which it is used by him. The Act goes on to say—"Party structure" shall include party walls, and also partitions, arches, floors, and other structures separating buildings, stories, or rooms, which belong to different owners, or which are approached by distinct staircases or separate entrances from without." The provisions, so far as they relate to party walls, are of two classes—those which regulate the nature of the construction, and those which fix the rights and duties of the respective owners of a wall with respect to each other. Part 2 of the Act, which relates to "dangerous structures," has also an important bearing on party walls. The first class includes such things as have to be done under the supervision of the district surveyor. With respect to them much misapprehension exists, but where carefully studied they become tolerably clear. I only propose, therefore, to bring them together in a form convenient for discussion, and such as will form an introduction to the much more troublesome and difficult class of provisions which relate to building, and adjoining owners. By Section 27 of the Act every building must be separated from every adjoining building by two external walls, or one party wall, and under particular conditions of size and occupation the other party structures above defined must be used. By Section 9, any "alteration, addition, or other work," which affects the construction of a party wall is subject to the regulations of the Act. Section 10 provides that whenever more than one-half of an old building has been taken down, every part of the remainder of it that is not in conformity with the Act must be taken down; and Section 11 provides that whenever as much as one half of any timber or other partition not in conformity with the Act, and separating old buildings, is removed, the buildings must be divided from each other as directed by the Act. The first schedule of the Act gives the thickness of "external and party walls" with reference to their lengths and heights, the height (for this purpose) being measured from the base of the wall to the level of the top of the topmost story, which means the under side of the tie of the roof, or half the vertical height of the rafters where there is no roof tie. But the party wall must, by Section 17, be carried up above the roof, flat or gutter of the highest building adjoining thereto, so that it shall be 15in. above the flat or gutter, and 15in. from the roof, when measured at right angles to its slope. If any turret, dormer, lantern light, or other combustible erection be upon the roofs within 4ft. of the party wall, the wall must be carried up 12in. above such erection, and be 12in. wider on each side than it is. Also the wall must be carried up above any part of a roof that is opposite to, and within

* The Dangers of our Sewers and House Drains, with Means of Removing these Dangers. By W. COPLEY WOODHEAD, M.R.C.S., Leeds.

4ft. of such wall. By Section 13 recesses may be made in party walls, but the backs of these must be 13in. thick; they must be arched over, must not come within 1ft. of an external wall, and must not extend over more than one-half the area of the party wall. Section 18 forbids that a chase cut in a party wall should exceed 14in. in width, or 4½in. in depth, or should leave less than 8½in. of brickwork at its back, or should be within 7ft. of any other chase on the same side of the wall. By Section 28 any opening made in a party wall for the purpose of uniting two buildings which together would contain over 216,000 cubic feet must be not more than 7ft. wide and 8ft. high, and the floor jambs and head must be of brick, stone, and iron, and have two wrought-iron doors, each ½in. thick, separated by the full thickness of the wall, each fitted in rebated frames without woodwork of any kind. Buildings so united must be in the same occupation, and when they cease to be so occupied the openings must be built up. By Section 20 the back of every chimney opening in a party wall must be 8½in. thick from the level of the hearth to 12in. above the mantle, and no chimney breast or shaft built with or in a party wall must be cut away without the certificate of the district surveyor. Sections 24 and 25 fix the thickness of the party arches which have to be constructed to separate different properties. As to timber in party walls, by Section 15 the ends of bressumers and of beams or joists if bearing upon party walls must be 4½in. from the centre. Bressumers must have stone or iron corbels under them, and must have 4½in. piers or else story posts under them in addition to their bearing on the party walls. The foregoing regulations will help to a right understanding of that part of the Act which deals with the rights, duties, and powers of the respective owners of party structures. These are the subjects of constant dispute, often leading to grave annoyance and loss; it is therefore highly important that from the first step everything relating to a party wall should be conducted with careful reference to this part of the Act. But, in fact, this is very often neglected, the whole proceeding being carried on without regard to the law, or in reliance on the good nature of the respective parties, although as neighbours they are in a position of natural antagonism to each other. The following considerations will show that such a practice as this is unsafe, and ought never in any case to be followed. Laws are made to be observed, not to be ignored. A client has a right to expect that, when there is a well-known mode of procedure legally established, that mode shall be followed by his architect in every particular. Although he will give no special credit if everything goes well, he will have a right to complain if they go badly. There is always a great risk that some complication will arise even in the simplest matter, especially if it is known that it is being loosely managed, for then either party may see his way to gain something by taking advantage of the want of strict management; even where all parties wish to be fair it often happens that owners of property are so nervously anxious about it, that they think every one that touches it is doing them mischief. Then the parties may quarrel during the progress of the work, or they may die, when their successors would be neither legally nor morally bound to adopt any arrangement not legally made. It very frequently happens that parties are only limited owners, being lessees or tenants for life, or they may be trustees for parties who will hold them responsible for any damage to the property. If the owners are a public body their officers will not be justified in allowing anything less than the strict fulfilment of all legal requirements. If any loss is caused through irregular proceedings the architect or the builder may find himself saddled with the whole responsibility for damage caused in executing works which he had no more real authority to do than any man in the street. Lastly, it is generally quite a little trouble to do what the law requires as to manage the matter in any irregular way. The owners of a party wall are called "tenants in common" of the wall; they are not owners each of the half wall which stands on his ground. Where there was no Building Act either owner could pull down the whole if he thought he should like to have a better

one. The only foundation in the Act for this idea of separate ownership seems to be in the interpretation of the word "area," which, as regards a building, is to include "such portions of the party wall as belong to the building." Party structures, considered as belonging to different owners, are dealt with in Part III., beginning with Section 82, which enacts that such one of the owners of the premises separated by or adjoining to any party structure as is desirous of executing any work in respect of it shall be called the building owner, and the owner of the other premises shall be called the adjoining owner. Now, the "owner" (by the interpretation clause) applies to "every person in possession or receipt either of the whole or of any part of the rents or profits of any land or tenement, or in the occupation of such land or tenement other than as a tenant from year to year or for any less term, or as a tenant at will." At an early period, often before the old building is pulled down, the building owner should cause a party-wall notice to be served on every adjoining owner, and as the work to be done may not as yet be finally settled, it is wise to include all the matter which a building owner can do in the notice. There is often great difficulty in finding out the real owners; a weekly tenant will represent himself as a leaseholder, or a bona-fide leaseholder may have so short a term that he will be gone before the notice expires. As a rule, it is best to serve a notice on everybody who seems to have any interest in the property, for if they are not owners, the notices will not make them owners. The notices usually bring all parties to some arrangement. If there is a leaseholder he being responsible to his lessor most usually and properly, is the party solely dealt with, but the freeholder will sometimes insist on protecting himself also by an award. The notice is printed and sold by authority of the Metropolitan Board of Works, and is usually filled up and served by the architect of the building owner. I suppose it is intended that this ordinary matter may be properly managed without its being necessary to take legal advice and incur needless expenses. As it cannot be properly said to be the architect's business, he had better strictly limit himself to such cases as are quite plain and clear, and if there is the least doubt as to the proper parties on whom to serve notices (as there must often be in the case of trusteeships and of companies) he should let his client's solicitor take the responsibility. The same may be said when the clients are trustees or a company. The notice must be given to the adjoining owner three months before any works can be done, by delivering the same to him personally, or by sending it through the post in a registered letter at his last known place of abode. All other notices or requisitions must be served in the same way. The architect is usually named in the notice as the surveyor appointed by the building owner to superintend the work, and to settle on his behalf all matters of difference that may arise in relation thereto. This is convenient, but not necessary, for the building owner is not bound to appoint a surveyor until he has received ten days' notice from the adjoining owner to do so. It is very common to receive a party-wall notice signed by the architect on behalf of the building owner which is invalid, and if any difficulty arises, his client may disown him. It is also common to name as "the surveyor" a firm of architects, instead of that member of the firm who intends to act: in these cases the appointment is invalid. We have nothing to do here with the motives which may often render it desirable for the building owner to keep the exact nature of his intended operations secret as long as he can—such, for instance, as his possible interference with ancient lights. But as a rule it is only courteous to let the adjoining owner know, if he wishes it, as soon as possible, what is to be done, for it may happen that some of the works included in the notice will so seriously interfere with his property that long notice and arrangement with other parties is necessary. I have had cases where the nature of the occupation of adjoining premises was such that it was found better to build a new external wall than pull down and rebuild the party wall. If the adjoining owner does not within fourteen days express his consent to the

notice, "he shall be considered to have dissented therefrom, and thereupon a difference shall be deemed to have arisen" between the parties. It is as well that this difference (which is almost inevitable) should be allowed to arise thus by lapse of time rather than by writing a formal letter, which may convey the idea that serious obstruction is intended. After the lapse of this time the adjoining owner may appoint the surveyor who is to act on his behalf, but he is not bound to appoint him until ten days after he has had formal notice to do so, for the original party-wall notice does not ask him to appoint a surveyor, though many persons seem to think it does. If either party makes default in appointing his surveyor after this ten days' notice, the party giving the notice may make the appointment in the place of the party making default. The building and adjoining owners may concur in the appointment of the same surveyor, who in that case has the same powers as the two surveyors and the third surveyor whom they are required to appoint. This appointment is very often neglected; a surveyor who desires to obstruct will avoid it. It is, however, the first business to be done between the two surveyors, whether they are going to agree amicably or not. He will naturally be some person who both parties believe will act fairly and impartially if required. If either party refuses to join in the appointment of the third surveyor there is nothing in the Act to compel him to do so; it is a matter for legal advice, but it is a very unusual course to take. On this point I would remark that it does not seem the duty of surveyors, when placed in the position of arbitrators, to exercise their ingenuity in placing obstructions in the way of the other side, as if they were solicitors instructed to fight a matter to the uttermost. They are appointed to see that the difference is fairly adjusted, and that is all that either side can honestly desire. The appointment of the third surveyor should be in writing, signed by both parties, although he may never be called upon in the matter. Indeed, I believe that the Act is clear that he must at least be appointed, for the 7th clause of the 85th section says that the "one surveyor" (agreed on between the parties) "or three surveyors, or any two of them, shall settle any matter in dispute." So that they must be two of three, and not simply two. Observe also that the third surveyor is not an umpire, as is often imagined; he can only act with one or both of the others, and in cases of very great difficulty and responsibility he had better be joined with the other two for the security of all parties, and to show that every care had been taken to arrive at a proper decision. The duties of the surveyors are "to settle any matter in dispute between such building and adjoining owner, with power by his or their award to determine the right to do and the time and manner of doing any work, and generally any other matter arising out of, or incidental to, such difference." But as they have no power to award that the work shall be begun before the expiration of three months from the date of service of the party-wall notice, which requires the permission of the adjoining owner himself, there is an appeal within fourteen days to the county court, which brings the matter into the hands of the lawyers, where we may very well leave it. The award must not deal with anything beyond the Act, and if in carrying it out injury is done to ancient lights of the adjoining owner, it will not protect the building owner from the consequences thereof. We find the rights of the building owner defined in the 83rd section. The Master of the Rolls recently laid down in a case in which I was engaged, that this section contains all his rights, and that within the area affected by the Act he had no others. The 88th section regulates the apportionment of the cost of works that may be done, and it will be convenient to read the two sections together.

1. The building owner may repair any party structure that is defective or out of repair, and the cost in such case must be borne by the two owners in due proportions, regard being had to the use which each makes of the structure.
2. He may pull down and rebuild, if it is so far defective or out of repair as to make this necessary or desirable, on the same terms as to the cost.
3. He may pull down any timber or other partition dividing the building that is not con-

formable to the Act, or to either of the two older Building Acts which next preceded this Act, and build a proper party wall instead, each owner bearing his due proportion of the cost, according to the use he makes of the wall, and also to the thickness of wall which his building requires. 4. He may deal with intermixed property; and, 5, with buildings communicating over public ways, which will involve very complicated questions not relating to party walls, and which may therefore be passed over here. 6. He may raise any party structure permitted by the Act to be raised, or any external wall built against such party structure; but as this would be solely for his own convenience he must bear the cost, and must, besides, make good all damage occasioned to the adjoining premises, or to the internal finishings and decorations, and carry up all flues and chimney stacks of the adjoining owners so far as the new works may render it necessary. 7. He may pull down any party structure that is of insufficient strength for his intended building, and may rebuild it of sufficient strength, on the like conditions as to cost and as to making good damage to adjoining premises, their internal finishings or decorations. 8. He may cut into any party structure at his own cost, and on condition of making good damage to adjoining premises. 9. He may cut away any footings, chimney breast, jambs, or flues projecting from the party-wall, in order to build an external wall against it, or for any other purpose, on the same conditions as to payment of cost and damage; and although they, being upon his side of the wall, may be considered his own property, he cannot deal with them without a proper award under this Act; nor can he cut away the chimney breasts or shafts without the certificate of the district surveyor, as already pointed out. And after the external wall has been built the party wall remains a party wall, which may cause future trouble to either owner, or to both. Finally there is a very comprehensive clause giving the building owner a right to perform any other necessary works incident to the connection of party structures with the premises adjoining thereto. It will be seen that there is very great scope for the exercise of the judgment of the surveyors on most of these points. There is the just apportionment of costs when work has to be done at the expense of both owners. Where the respective buildings differ greatly in size, and the party wall, which would be thick enough for one, has to be built thicker in respect of the larger building, the exact position of the centre of the wall with respect to the line dividing the two properties may have to be fixed separately for each floor. As there are certain parts of the metropolis where the space in a building, occupied by a thickness of only 4 in., more or less, in a party wall, would be worth several hundreds of pounds, the importance of this arrangement is evident. Besides this, questions as to what damage has been done to the premises of the adjoining owner, his finishings and decorations, and the value thereof, are often very complicated. No power is given to make the building owner hoard up or pay for hoarding up the rooms of the adjoining owner that may be left open by pulling down the party wall. No award, therefore, can deal with that particular item, whatever remedy might be found by action at law—a not very promising proceeding. If the building owner fails to make good any damage done he is liable to a penalty not exceeding £20 per day, at the discretion of the magistrate. Although power is given above to raise a party wall no power is expressly given to underpin or to continue the wall downwards—an operation frequently requiring to be done, and included in a party-wall notice. I think we may draw a distinction between an ordinary act of underpinning, where such work is necessary by reason of the base of a wall being decayed or placed on a defective foundation—which act is of the nature of a repair—and the act of extending a wall downwards for the purpose of forming a basement of one or more stories in depth below the old foundation. The Master of the Rolls, in the case to which I have referred (*Standard Bank v. Stokes*), had all this before him, and gave the opinion that the power given to raise a wall is wide enough to include this downward extension of it. He

said—“Is it necessary to limit the word ‘raise’ to putting something on the wall on the top? And may not you raise or make it longer, or build it up by something on the bottom? I do not think it necessary so to hold.” He considered also that, having power by another subsection of the Act, to pull down a wall and put it up again, it would be an extraordinary reading of the Act to say that you may not do something less—that is to say, support it, and put a new wall underneath it? But the judge founded his decision on the power which is given “to perform any other necessary works incidental to the connection of party structures with the premises adjoining thereto.” He said—“If you make the sub-basement, and you do not support the wall, it will fall down, and it is incident to its connection, because if it fell down its connection would be terminated in a very summary manner.” If one may presume to choose between these three reasons I should say the last seems to be the best.

(To be concluded next week.)

FARM ARCHITECTURE.*

FARM architecture occupies a position between domestic and plain utilitarian or engineering construction which has but few attractions for the architect whose sympathies attach themselves solely to the more artistic or decorative side of his profession. Hence it is not perhaps strange that the design and planning of agricultural buildings have been of late years relegated to a special class of professional men. At present the design of farm buildings is regarded as a kind of *tertium quid* best left to the agriculturist or farmer himself, and about which there is little to require architectural aid. This kind of unconcern has, however, a danger in it, for as we have pointed out in these pages before, the architect is losing ground by allowing a branch of specialists to take away a source of profit which for centuries has been a legitimate branch of his calling. Specialism will of course increase as the requirements of society become more numerous and complex, but as we have those who devote themselves to churches and schools, houses and mercantile wants, so there is ample room for many of the younger members of the profession to study the requirements of the farm, and make themselves competent to throw a charm round our farmsteadings and rural buildings. If furniture, carpets, and wall-hangings are worthy of the architect's attention, we do not see why his pencil and artistic power should be withheld from a class of buildings which represents so important a field of British industry as that of farming and agriculture. An additional reason why we think the subject is one not unworthy of his skill is, that of late years many improvements and systems of husbandry have been introduced, and that the old farm-steading, picturesque as it often was, is being fast superseded by a more scientific and less pleasing arrangement which it is within the true architect's power to recast into more artistic forms. What, for instance, could be a more appropriate subject for those architects who are reviving the old English homestead, than the farm with its group of sheds and buildings? We are prompted to make these remarks by a small octavo volume lying before us entitled, “Practical Architecture as applied to Farm Buildings of every Description,” written by Mr. Robert Scott Burn, farm architect and engineer, and the author of several works on similar subjects. The book is a reprint from a series of articles that have appeared in our contemporary, the *Country*, and will be found a most useful guide to the planning and construction of farm buildings. The author has given a careful digest of the practical details of farm construction rather than a comprehensive treatise on general principles. After generally referring to the three systems of farm planning known as the “compact,” the “grouped,” and the “isolated or detached,” the arrangement and details of stock buildings are discussed. Two or three forms of cow-houses or “byres” are illustrated, and of course in all of them the feeding passage is recommended both for the purpose of

keeping the cattle quiet and also for the cleanliness thereby insured. For small houses, where from four to eight cows are kept, the sheds are about 18ft. to 22ft. wide, out of which there is a 3ft. 6in. feeding passage, a 5ft. 9in. length of stall, a space of 5ft. 6in. in front, the cleaning or dunging space next the wall, and a 9in. gutter between. In the double-stall arrangement the cattle are placed head to head in two rows, with feeding passage down the centre. Another double arrangement shows a duplication of the first single row plan, the stalls being placed in rows along the front and back walls with passages for feeding close to the walls, and the dunging passage down the centre of shed bounded by gutters on each side, and laid slightly convex. The latter plan is recommended as the best for large cow-houses, especially where the proprietor desires the dunging to be done quickly and economically, as the manure is then carried off through a centre door in the end wall. Both systems, however, have obvious advantages over the single plan, which are discussed. Various details are entered into, and we may refer to the suggestion that single stalls are preferred to those for holding two cows, and the author justly says stalls are generally made too narrow, and he advises about 4ft. 6in. as the best width. As regards floors, Portland cement, concrete, or asphalt, are spoken of with more favour than stone or brick, which last materials are hard and uncomfortable for the cattle if laid at the top part of stall. Channels or grooves cut obliquely to a centre groove leading to the main gutter or simply inclined floors, are certainly less troublesome than sparred or open timber frames with space underneath into which the dung falls—a mode preferred by some feeders. We are certainly inclined to agree with Mr. Burn when he questions iron fittings for the “travis” board or division between the stalls. They are certainly not so comfortable nor warm as wooden fittings for the cattle to come in contact with, and if the heel and head posts were made of iron with rounded edges, all that can be desired is at once accomplished. The author humanely hints that much infliction of suffering would be prevented if these posts and all door posts had their sharp corners taken off. Another important suggestion is that the stall boards should be fitted loosely in the grooves of the posts so that they can be removed for cleansing, &c. All corners, as those between the walls and floors, facilitate cleaning if rounded off in concrete and cement. Coming to mangers or feeding troughs, the high manger is preferred to that resting on the floor; cast iron and earthenware are both used, and the water-trough should be provided with a tap from an overhead water-pipe. Houses for fattening cattle are thoroughly discussed, and the plans known as the “stall-feeding system,” the “box” system, and the open court and shed are described. These plans are the results of experience in accommodating cattle to be fattened for the market, and are roughly divisible into two classes. First, those in which the animals are confined to a limited space, as in the stall and box; and second, those in which space is given to allow them freedom of movement, such as the “curtain,” and open court, and shed system. The author quotes various authorities on each side, but it certainly appears to us to be a species of cruelty to adopt the cramped stall plan in preference to the “loose box” or “open court and shed system,” while economically the latter plan is quite as cheap as the stall. Various plans are given, illustrating the different systems. Thus the boxes may be arranged in double stall fashion, with a centre feeding passage under one roof, and with the turnip store at the end, or on each side of the straw barn. The boxes are usually 10ft. square or 12ft. by 8ft. The open court plan consists of a square-walled court about 36ft. square (if intended for six animals) with a lean-to shed on one side 10ft. wide, both concreted and drained, the turnip store occupying a central narrow shed between two such blocks. The “hammel” plan consists of a smaller court and shed intended for one animal, but in both systems it seems to us the animal has a natural freedom—can feed himself or drink when he desires, and keep his body in a more even temperature than possible in a close byre. At least, the

* Practical Architecture, as Applied to Farm-buildings of every Description. Profusely illustrated. By ROBERT SCOTT BURN, Farm Architect and Engineer. London: The Country Office, 170, Strand.

testimony quoted in favour of the open hammel as the more sanitary condition is overwhelming.

We pass over some sensible remarks on stable arrangement, and we are glad to find it stated that the balance of modern opinion points to a feeding passage at the back of stalls as a far more reasonable mode of replenishing or cleaning the manger than the old-fashioned one. Another point we may note is that 18ft. is the least width with such provision. Plans of a double arrangement similar to the cattle houses are given. Speaking of sanitary details, iron fittings and non-absorbent walls, or glazed-tile-lined walls are, of course, spoken of approvingly, and a kind of window in which the lower half is hinged like a casement and the upper half pivoted or hinged at bottom, is recommended. Rounded edges to doors and door jambs and fittings, flush bolts and latches, doors opening outwards, and a good width—the minimum stated is 3ft. 9in. by 7ft. 6in.—are, or should be, almost unnecessary precautions to be insisted on. As regards ventilation, the open louver-bearded ridge ventilating roof is now acknowledged the best, and the author concurs in the commissioners on barrack recommendations in these respects. The plan in favour is a double-stall arrangement, with a wide centre dunging passage between, open drains and channels being preferred. For the ingress of fresh air, ventilating bricks, 9in. by 6in., may be introduced between every two stalls, the air being conducted near the floor. We are sorry the author should have given the architectural details, as they are below criticism. The arrangement and construction of piggeries, sheep shelter sheds, poultry houses, and barns are subjects into which the book under notice enters, and some very good hints are given on the details of barn construction. As regards barn doors, the sliding system is coming largely into use, the door being suspended with rollers upon a rail at the top, along which it runs or is made to run upon rollers and a bottom iron rail. Corrugated iron doors are better and more economical when thus made. Concrete floors are also new generally esteemed for corn barns as being vermin proof and more economical, and various methods are detailed by which the cunning and perseverance of rats may be thwarted. Thus rats will often burrow from the outside round the bottom of the footing of wall, but if a course of stone be built into the wall below the ground and project a few inches, their progress will be obstructed and they will retire. A layer of concrete inside or outside the footings will also form a good check. Another good plan is to groove the board or concrete paving into the wall. Again, a useful kind of check is to hang cast-iron or zinc hoods or caps, with a projecting outer lip bent downwards, placed over the door steps and window sills, so as to stop the entrance of these rodents; and the timbers of the roof at their junction with the wall, such as the rafters and principals should be bedded in hard-setting mortar, and the corners cemented. Referring to the designs and plans given for country houses and cottages, we may say this is the least successful part of Mr. Scott Burn's little treatise, and his book would have been equally valuable without this section. The author prefers what he calls the "break and projection" type of house as the most economical, and this type forms the ornament to the cover of the book. We should rather call it the cruciform type, but we are not disposed here to controvert the merits of this arrangement. In the other parts of the book the author has furnished a fund of very useful data, to which the builder of farm-steadings may refer with profit, and we can with confidence say that every detail modern improvement can suggest will be found discussed.

PROPOSED NEW METROPOLITAN ROUTE FROM THE SOUTH TO THE EAST-END.

PROPOSALS for relieving the traffic over the Thames from north-east to south-east continue to be made, and we have already noticed one or two schemes. We have now another idea proposed by Mr. H. J. Lanchester, architect, of Abchurch-yard, Cannon-street, and that is to form a new route, chiefly for heavy goods traffic between the south and east of London, so as to divert it from the main

city streets. The idea is a good one, for we have all along considered that if the heavier traffic could be separated from the lighter or passenger traffic by a distinct channel, much of the overcrowding of our city thoroughfares, at their crossings especially, would be avoided. The author of the scheme before us observes with truth that the requirements of pedestrians and carriage-passengers have not been considered, although forming the most numerous portion of the traffic. At the crossings in King William-street and Prince's-street, Cornhill and Gracechurch-street, the congestion of both kinds of traffic is becoming daily greater and more dangerous, and the reason undoubtedly is mainly owing to the crossing of traffic running east and west with that north and south. The new route commences on the south side in the High-street, Borough, a little to the south of the junction with Southwark-street, passes through the Borough-market, crosses the Thames by a low-level bridge between Cannon-street railway-bridge and London-bridge, and terminates at Upper Lower Thames-street, at a point 100 yards east of the Cannon-street Station, at which junction a square is proposed of sufficient size to allow the traffic to pass freely east and west into Thames-street, which thoroughfare eastwards is proposed to be widened to an average width of 60ft. on the north side, diverted slightly to the north at the east end of Custom-house, by a new roadway into Trinity-square, avoiding the steep rise of Great Tower-hill. This route is shown to end at the Mineries, where the traffic will become dispersed into the main eastern thoroughfares. There is something to be said for this proposal, and the principal feature in it that commends itself to us is that it provides a separate channel for the heavier part of the traffic from the Surrey-side to the London Docks and East-end. The approach to the proposed bridge ends at Thames-street, and there is no direct access through into Cannon-street, so that the traffic going east or west will not be interfered with. The new route passes Billingsgate-market, the Custom-house, and Coal Exchange and various depots of manufacture and trade, and provides access to the docks, and the manufacturing establishments in the East of London. At the same time, would not a bridge at the Tower site give better facilities (by obviating the detour westwards) than that sketched? As regards the figures quoted by Mr. Lanchester—viz., that the average traffic per day over London-bridge is composed of 7,800 vehicles devoted to goods traffic, they certainly appear to lend support to a bridge further eastwards than that shown, especially as the greater part of the goods traffic is acknowledged to move in an easterly direction. Indeed, we hardly think a bridge in the situation shown, so near London-bridge, would be an improvement. If the East of London and its heavy traffic are to be relieved, why not boldly construct a bridge in the direction of the greatest need, instead of crowding up the river above London-bridge? Into the details of the scheme it is unnecessary to enter, though the author shows that the gradients of the new route would be very easy—1 in 55 on the south side, and 1 in 60 on the north—and compare favourably with the gradients to the approaches of London and Southwark bridges, which range from 1 in 22 to 1 in 34. We may add a lattice-girder bridge is proposed, 42ft. wide, of low level, and having a headway above Trinity high-water mark of 23ft. in the centre. No cost is stated; the approaches would run into a considerable sum, but with any scheme the item of purchase would be largely compensated for by the creation of business frontages.

METAL BAR & IRON BRIDGE STRESSES.

IN a paper printed in the transactions of the American Society of Civil Engineers, read by Mr. Theodore Cooper, C.E., member, some remarkable experiments are recorded upon steel bridge links. The writer noticed accidentally that the link heads, while being tested, exhibited peculiar markings due to the cracking of the scale while under the test. A closer examination convinced him that these markings indicated the mode of transfer of the stresses about the pin-hole, and throughout the head of the bars. It appears the links were of

steel, known as "Hay's steel," and were forged from solid billets by Messrs. Hussey, Howe, and Co. The section of one link in the body of bar was 3in. by 1½in., and that of heads 7½in. by 1½in.; the length from centre to centre of pin-holes, 2ft. 9in.; diameter of pin-holes, 3in. At 43,350lb. per sectional inch the scale began to fall off from body of bar, and the markings appeared. Another test on a duplicate link indicated very similar results. No permanent set was visible at 40,000lb. per square inch; the scale commenced falling at 45,700lb. At 47,000lb. per square inch distinct lines appeared upon body of bar. Relaxing the strain it was noticed about 2in. of the bar was distinctly marked with diagonal cross lines at 45° (as well as could be judged) to the line of bar, and these markings were visible upon all its four sides, the number of lines being about five to the inch, measured perpendicularly. Sketches are given of these lines, which, in the case mentioned, form quite an ornamental band of plaid-like form round the bar. The author also refers to other eccentric lines which appear about holes punched in steel plates, and several of these steel specimens are illustrated in the paper before us. We note especially one diagram of a flat bar grooved in centre, upon which quite a symmetrical disposition of crossed curvilinear lines is shown obtained upon a number of specimens of the same shape. Though no single specimen showed all the markings here given, each showed a portion, and these have been combined in the diagram before us. In the centre on both sides of the groove or notch, the lines represent intersecting curves somewhat like the pattern on engine-turned watch-cases. These appear first at about 40,000lb. per square inch on the grooved section. The markings about the pin-holes, near the end of bar were obtained at or near the rupturing point usually from 89,000lb. to 95,000lb. per square inch. The lines produced from shearing a steel plate are indefinite, showing the different kinds of strain due partly to shearing and partly to bending. These lines, it is noticed, cross one another at right angles, and are at 45° to the line of applied stress. The author thinks the direction of the transferred stresses upon these specimens are at 45° to the markings. Into the discussion that follows we cannot here enter, but simply remark the conclusion arrived at. This is, that the scale markings are lines of greatest shear, lines along which the metal slides to restore an equilibrium between the applied and resisting forces or lines of flow. The principles being accepted, the author concludes by asking whether we cannot plot the lines of transferred stress from these markings by drawing a resultant line of 45° to the several lines of shear, or that transverse dimensions may be taken so uniformly that the shear will be uniform throughout, and the form obtained be of equal strength at all parts.

In another discussion on the "Relative Quantities of Material in Bridges of Various Height," at the tenth annual convention, upon Mr. Emery's paper—a notice of which was given in the BUILDING NEWS of last year—Mr. W. H. Searles made a remark which corroborated the theory that high-trussed bridges were the most economical. The speaker referred to the Erie Canal bridges, designed by Mr. Squire Whipple, with a small height of truss, which were wearing out so rapidly, especially in the lower chord, from decay, that iron chords had to be substituted, the other parts being rebuilt in wood. Mr. Searles discovered that the low truss required an excessive amount of iron in proportion to the rest of the bridge. He thereupon raised the truss from 7 or 8ft. in a span of 80 or 90ft. to 16ft., with the object of reducing the cost of the iron chord. The author found from Mr. Emery's data that 16ft. was the most economical proportion at the then prices of wood and iron, comparing the cost of the 8 or 9ft. truss with the 16ft. one, and he found that in a small bridge of a single roadway, there was a saving of about 100 dollars. The increased height necessitated counter-bracing of every panel, and a system of overhead-bracing was also required, but the result is stated to be very satisfactory, and the bridges are crossed with a greater sense of safety than the lower-trussed ones.

SOUTHPORT GLACIARIUM.

This glaciarium has been erected to provide for the rapidly-growing town of Southport a cold store for the preservation of meat, also a manufactory for pure ice, and the largest sheet of ice for skating that has ever been produced by artificial means, which will add much to the attractions of this favourite seaside resort. The skating hall is 160ft. long \times 64ft. wide, the area of the ice being 144ft. \times 54ft., or 7,776ft. sq. The front buildings contain large cloak-rooms, lavatories, and skate and refreshment-rooms, with a large gallery for spectators across the end of the hall. In this building are also provided, separate from the hall proper, spacious billiard, dining, and reading-rooms, with photographic studio, &c. At the other end of the building, and in communication with the skating-floor, is a beautifully-arranged fern-grotto promenade. The front is faced with red pressed bricks, carved and moulded. The engine-room and boiler-house are in the rear of the building, and contain machinery of the most improved character for the purposes of refrigeration. It is contemplated to still further extend this portion of the premises and plant. The buildings have been designed by Messrs. Bell and Roper, of the Royal Exchange, Manchester; Mr. T. Bridge, of Southport, being the contractor. The glaciarium is the property of a company formed to carry into practical effect the patents of Professor John Gamgee, and the warmest praise is due to Mr. Edward Holden, the chairman, and his co-directors, for their intelligent perseverance in the execution and accomplishment of their difficult task. The building was formally opened by Mr. Edward Holden, on Friday, the 10th instant, and on Thursday, the 16th inst., the skating-floor was inaugurated by Lord Lindsay, followed by a curling match between the Lancashire clubs.

WINGFIELD MANOR, DERRYSHIRE.

MR. LANGHAM gave some general historic notes of this mansion at the time of publishing his sketch of the porch and chapel gable. (See BUILDING NEWS for September 15, 1876, Vol. XXXI., p. 257). This bay window is on the same side of the inner court as the porch, and to the right (all the intervening wall being razed), and lighted the great hall. The jambs or side faces of the bay are not square, but slightly splayed, so that the plan is half of an irregular decagon. The door shown opens on a stair down to the finely-vaulted crypt.—W. R. LETHABY.

CHURCH OF ST. BARNABAS, BECKENHAM.

BECKENHAM is among the foremost of the rising suburbs to the south of London, and house-building has recently been carried on very extensively. Such an increase has of course necessitated further church accommodation, and it is but a short time since that we published (June 29, 1877) a view of Holy Trinity Church, a building of very considerable merit. To day we give a view of the new Church of St. Barnabas, from the designs of Messrs. Stenning and Hall, architects. We have received no particulars of the building.

HOUSE AT CLAVERTON.

THIS is a residence recently erected at Stoke Bishop, near Bristol. The accompanying drawing indicates the general style of the building. The walls are built of red bricks, and are hollow. The dressings are of Douling stone. The roof is covered with Broseley tiles. The exterior woodwork is of deal, and painted a chocolate colour. Of the interior woodwork, that in the hall, including the staircase, screens, and panelled ceiling, and that in the dining-room and studio, are of pitch pine stained (not varnished) a dark colour. The other woodwork is of common deal and painted. The terrace walls are of red bricks, some being of special make. The stabling is situated at the south-east side of the house, and is built in the same style as the house. Mr. Wm. Wood Bethell, of 19, Craven-street, Strand, London, was the architect; Mr. J. E. Davis, of Bristol, the builder; and Mr. Ed. Honey the clerk of the works.

CHURCH OF ST. MICHAEL AND ALL ANGELS, BEDFORD-PARK, TURNHAM-GREEN.

LAST week we gave the general geometrical drawings of this interesting building, and to-day we are enabled to publish several details to a larger scale, including the nave and aisle roof and benches in the nave. The drawings are carefully figured, and descriptive notes are given with the several parts, so that further description here is unnecessary. Next week we hope to conclude our series of illustrations of the church by publishing a perspective view with ground plan, a longitudinal section and details of the aisle window, buttresses, &c. We understand that a parsonage house is to be built adjoining the church. Mr. R. Norman Shaw, R.A., is the architect of all the buildings on the Bedford-park estate.

ALL SAINTS' CHURCH, STOKE NEWINGTON.

THIS church is situated in Aden-grove, Stoke Newington, and was erected a year or so since from the designs of Messrs. Francis T. Dollman and William T. Allen, architects, of the Adelphi. We publish a general plan with the view, but no particulars have been received from the architects. Our illustration is taken from the drawing which was last year exhibited at the Royal Academy.

SCHOOLS OF ART.

GLASGOW.—The annual meeting for the distribution of prizes in connection with the Glasgow School of Art and Haldane Academy was held last week in the Corporation Galleries. The annual report of the committee of management stated that for 1877 the number of students was 1,167, and for 1878 1,003. Of these 322 presented themselves at the local examination, of whom 144 passed. The branch school in the East-end had been well attended. The financial position of the school was fairly satisfactory, but the committee noticed with regret a decrease in the amount of subscriptions.

COMPETITIONS.

HALIFAX.—At the last monthly meeting of the Halifax School Board a report of the board in committee was presented, showing that at a meeting on the 13th of January, at which nine members were present, the plans selected from 92 competitors for the erection of a higher board school were those submitted under the motto "Seal of the Board," the second premium of £25 being awarded to the author of the plans under the motto "Prussian." The sealed envelopes accompanying the plans having been opened, it was found that Messrs. Leeming and Leeming were the authors of the plans under the motto "Seal of the Board," and Mr. Richard Hershall of those under the motto "Prussian." It had therefore been resolved in committee to authorise Messrs. Leeming to obtain tenders for the works required to be done in the erection of the entire school, according to their plans, and also for the erection of one department only. Mr. Ramsden inquired how the voting was in committee upon the subject, and in reply the clerk said there were five in favour of the report, three against, and one neutral; whereupon a discussion ensued upon the motion of Mr. J. W. Longbottom, seconded by Mr. D.

Hitchen, that the report of the committee be adopted. Mr. Ramsden thought, and he was supported by the chairman, that the majority of the board in committee was not a sufficiently preponderating one to warrant an immediate acceptance of their decision, and he suggested a reconsideration of the matter. After an opportunity had been given for the expression of opinion upon the subject, Mr. Longbottom replied, and characterised a reconsideration of the plans after their authorship was known as a proceeding which would not be endorsed by any honourable man. Ultimately the resolution that the report be adopted was put to the meeting with the following result:—For, Messrs. Longbottom and Hitchen; against, Messrs. Swallow, Snowden, and Ramsden; neutral, Messrs. Riley, Storey, and Drury. The motion was therefore lost, and the board resolved itself into a committee. If the recommendation of the committee is adopted finally it seems a pity that 90 architects have been put to trouble and expense for nothing. The two successful Halifax architects might just as well have been applied to at first.

ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The third meeting of the session was held on Wednesday last; Mr. Thos. Morgan, in the chair. The Rev. Mr. Chandler reported the discovery of the altar slab of Waterbeach Church. It is of grey marble, and has been supported by six pilasters, fragments of which were found. The peculiarity was noticed of the usual 5 incised crosses appearing on what seems always to have been the under side of the slab. Dr. Woodhouse, as a warning to antiquaries, exhibited a large collection of forged articles, the work of the firm of "Billy and Charley," whose productions were more frequently met with a few years ago. Mr. Loftus Brock, F.S.A., described an African jug of modern date, but having the form of colouring of early times, being an example of the continuance of ancient types in the country. Mr. Gordon Hills reported that several fragments of Roman date had been found in Chichester Cathedral, indicating the prior existence of Roman buildings on the site. He exhibited red tesserae and Samian ware, and spoke of flue tiles having been found. Mr. Hills then read the first paper, descriptive of the recent discovery of a remarkable series of earthenware vessels at Leeds Church, Kent. They are built up over the arches of the nave, and were inserted probably in the belief that they would help the acoustic effect of the building. The arches are of 15th century date, but the jars appear to be older. The subject of acoustic pottery in churches was dwelt upon at length. Mr. R. Blair described a great number of small articles carved in jet, found on the site of the Roman station, South Shields, and which are very peculiar in form. Mr. de Grey Birch, F.R.S.L., commented upon the peculiarities of the inscriptions. Mr. Roach Smith, F.S.A., reported the discovery, in the Allier, of the site of a Roman manufactory of small statuettes of white clay, and exhibited a series of photographs of the most interesting. These articles are of rare occurrence in England. Mr. Morgan read the second paper, taking for his theme the positions of the Roman armies in North Britain in the second and third centuries—the positions being indicated by numerous evidences which were passed in review, while recent discoveries were mentioned which afford additional information. The third paper was by Mr. W. C. Little, who traced the course of a Roman road across the Cambridgeshire fens, and described its construction of gravel upon a layer of branches. It is generally 25ft. wide.

The death is announced, at the age of 74, of Mr. Henry Nelson Hughes, builder, of Wrexham. He was largely concerned in erecting houses for the working classes, and built a number of dwellings of this character in Springfield, Rhondda, and subsequently bought a quantity of land in the hamlet of Rhoscerney, which he covered with houses. At the time of his death he was in association with his son, Mr. Charles Hughes, erecting 45 houses between Rhondda and the railway station. Mrs. Hughes died on the following day after her husband, and was buried in the same grave.

BUILDING NEWS DESIGNING CLUB.

A WAYSIDE INN.

THIS subject has taken well with our contributors, and we have some fifty designs, all bearing marks of study and painstaking effort, and some of much merit. We did not propose any condition as to cost in the present instance, but left every competitor to work the problem out himself. Many of the designs give us rather more of a suburban hotel or public-house than an unpretending wayside inn, and for this purpose or for a village inn they are suitable. Four or five designs closely contest the prize, but after due consideration of the conditions we have decided upon placing the design under motto "J., New Year's Day" as the first. Its unpretending and picturesque elevation is not, however, its chief merit. It is compact, cosy, and economical in plan, and it covers less area than most of the other plans which run it very close. The ground plan bespeaks the purpose; the lobby is sufficient, and opens into a taproom, well lighted in front, with seats round the walls. On the right is a small bar—not a tavern or railway buffet—served from a short corridor inside, which gives access to a snugery, a kitchen, and mainly to a bar-parlour in front; the latter is of good size, with a wide and well-lit bay and an angle fireplace placed in a convenient position for the comfort of wayside travellers. The conveniences are well placed, and the bedrooms small but sufficient. The author has simply treated the exterior in brick and tile, but has made a feature of the doorway and bar window which places it out of the rank of a cottage or dwelling-house. The tile-hung walls and the bay with tarred timbering and plaster above are pleasing and homely-looking. The next design, "Mechlin," we had intended to give the first place for its even more expressive inn-like character. No one can mistake it for anything else; its two end projecting gables timbered, and its bracketed gallery between, its spacious entrance and bar window are very characteristic of the public-house, and the drawings are carefully and cleverly executed, but the ground plan savours too much of the hotel in its dimensions and completeness. There was scarcely any necessity for a side tap entrance; the offices are not very conveniently planned in relation to the bar, and the rooms are larger than required for the chance custom of a wayside. The author says in a note, "Bar accommodation is only provided in connection with the taproom and skittle-alley, the better class of customers generally using the bar-parlour." The remark applies to a village inn. "Yesram" sends a more compact plan, but fails in the elevation. The bar has a counter cutting off quadrant-fashion the corner of the space—a mode of accommodation more suitable to and suggestive of a railway tavern. The bar-parlour and smoking-room are conveniently placed on each side, and the private part of the house is well cut off from the public portion. There is a side entrance for skittle-alley. The elevation reminds us too much of a fancy suburban tavern or a cottage *ornée*, and the entrance has a private air of seclusion, hardly characteristic. "S" in circle falls into a similar mistake in his elevation. Uncommonly pretty, neat, and nice, as a country lodge or residence, it is much too fanciful to be built by some desolate country roadside, with but little to set it off in the way of buildings. The chief fault we find with the plan, otherwise good, is the draughty passage and cramped stairs. The drawings are cleanly and neatly done, and the estimate at 7d. is worked out at £1,366. "S." is one of the few competitors who have furnished an estimate. "B" in circle is a cleverly drawn and pleasing cottage-like inn, the entrance being up a few steps under a sheltered lean-to of the roof placed sideways. The idea is certainly pretty and cosy, and the plan is skilfully managed as regards the bar and entrances; the bar parlour is approached through the bar—not perhaps desirable—and the smoking-room and dining-room would have been better thrown into one. The rooms are rather small. Another clever but misapplied study is "Triangle" in circle. It certainly lacks one essential, and that is character. Its elevation looks far more suitable for a builder's residence, with yard and workshops attached,

than a wayside tavern. It has a rather monumental doorway, and the style is more suitable for a stone district. The plan lacks invention and fitness. The kitchen is too far away from the bar, to which it has no connection, and the bar-parlour and smoke-room scarcely enjoy that privacy and immunity from the inquisitive eyes of the barmen or barmaids which a hungry wayfarer would look for. The straight passage divides the house uneconomically, and the idea of a town house is uppermost. A stable entrance is shown. "Omega," as usual, sends some well-designed elevations, pleasing in detail, but the plan has a crowded and confused look about it that almost defies unravelling. In the first place we do not see very clearly how the hall is to be lighted, except through the screen of bar; another fault is the distance from kitchen to bar, while the tap-room is too much cut off from the bar. Externally the design is suitably treated. "Omnia Vincit Labor!" This is a plan which scarcely seizes the main points; the bar is a mere cupboard-room, with small serving hatches between hall and bar-parlour; the kitchen is not in direct communication, and the arrangement is more fit for a village inn than a roadside. Externally the grouping is somewhat heavy and the treatment is too domestic for a public-house. The building is cubed at 7d. = £1,537. "Enigma" has some good points, such as the arrangement of bar and parlour, and the elevation, half timbered, is more suggestive of an inn than many others, but the communication between kitchen and bar is not handy. "J. S." is a carefully drawn elevation, but it becomes more a cottage *ornée* or a gentleman's lodge than a wayside inn. The plan reminds us of many railway hotels, and there is a want of fitness evident. "Fritz" seizes the idea, and his plan is not without merit, especially in the arrangement of bar and kitchen offices; but the roof is heavy, and the end elevation not happy. The author of "Be to its merits very kind, and to its faults a little blind" has sent a very detailed and elaborate set of drawings, in which flues and joists are shown—a work of supererogation on his part, the labour of which would have been better bestowed probably in improving the plan. One fault to which we can hardly be blind is the large bar and counter, and the want of communication between latter and kitchen. The elevation expresses its character, and the ample notes and scantlings interspersed—if unnecessary for our purpose—show at least a knowledge of detail and practical requirement that is commendable. The detail of chimney-piece is not without merit, but too elaborate, and the side ramps would have been better omitted. Many of the designs, in some respects clever, err in showing the arrangements of small public-houses. Among these we may place "Con Amore"—neat and typical in elevation, "Y." in circle, "Che Sara Sara," "M." in leaves, "Spero Meliora," "Herat," "Such a Dog," "Bad Attempt," "Cyprus," "Tam O'Shanter," "Anchor," "Nemo," a design with no motto, initials being A. W., Leeds, "Signum," and "Octagon." Many of these are creditable as elevations, and the drawings are meritorious; but in every case the author has aimed at a suburban hotel, or a class of building which we are accustomed to designate by the name of "railway hotels." In some of these there is a want of suitability both in plan and elevation. "Tam O'Shanter" is one of the best, though we cannot particularise the merits or defects in every case.

The other designs we have received partake more of private houses in plan and external treatment. We may name in this category "Ivy Leaf," in which the timbering is shown in a fashion that is more singular than beautiful; "Ich Dien," "Corona," "To be or not to be," "Spider," "Primo," "Star" in circle, "One of them," "Stefano," "B. M. W.," "Try," "Anchor" in circle, "En Avant," "W." in triangle, "Peter," "Ogmore."

DINING-ROOM BUFFET.

Of these designs the one with motto "J." is the simplest and most effective. The plan is canted at the ends, and there is no exaggerated or strained effort to produce quaintness or ornamentation. Below the buffet top the doors are framed in Japanese fashion—the panels

being enriched by painted plaques with heads, the surrounding panels having stamped crimson leather, and the mouldings being gilt. The dresser top has a back of bevelled mirrors—the upper lockers being carried by turned balusters at the angles. At the top of lockers is a railed shelf for porcelain, &c. The whole is proposed to be executed in English oak, unpolished, and gilded in the principal mouldings. The latter are in good taste, and there is refinement in the detail generally. In "J'Espere" we recognise a well-known hand. The design is a clever one, with a certain admixture of Japanese detail. There are three cupboards below with bamboo framework and tinted glass panels in lead. The centre opening has a curtain. Above are three drawers, and above the shelf is a simply-treated top, with shelves for *bric-à-brac*, and bevelled mirrors below. The ornament is proposed to be executed in black line, the centre cupboards being painted. Simplicity and breadth are somewhat sacrificed, though there is evident merit in the composition. We do not admire the finish of the uprights and cupboard stiles, which have a rather awkward appearance. The design "Memor Esto," has much simplicity about it, and there is a quiet Renaissance feeling throughout. There is a centre cupboard, a coved recess above the table top, with shelf above. The details are not equal to the design. "Frappe Fort" sends a rather ordinary-looking design, marked by a few good points—such as the cupboard details, the rack below, &c. The ornament proposed is appropriate, and there is the merit of simplicity in outline. We are glad to see "East Anglian" stand so well this time. His design is certainly quiet and dignified, and the detail markedly in advance of former efforts. Some good detail is observable on "Be to its merits very kind," &c., and the author has figured in the sizes of every part. We do not like the pointed-shaped legs to the upper shelves, and the centre panel is too cut up. We can only further name in order of merit a few others—"W. J. M.," "Burswell," "Try," and "J. S."—and in these we find evidences of improvement, though the prevalent weakness is attempting too much.

THE R.I.B.A. AT THE CRITERION.

ON Monday morning last, in accordance with the request of the President of the R.I.B.A., Mr. Verity, the architect of the Criterion, attended at that building to meet members of the Institute, so that the several details and arrangements of the various departments of this large restaurant—described by Mr. Verity in his paper before the Institute on Monday, the 13th—might be seen in working order previous to the discussion on the subject at the Institute's next meeting. The few members who attended the visit were amply repaid by what they saw, both in the Criterion and its theatre, as well as in the new building adjoining, which is to form so large an addition to the present accommodation. But it certainly betrays a want of taste and consideration on the part of the R.I.B.A. having—through its president—asked to be allowed to visit the buildings, that no one representative—not even the president or secretary—was present to meet Mr. Verity, and with the exception of two or three fellows, the meeting consisted of a few junior associates. At the visits of the Architectural Association care is always taken that two or three representative members or officers are present. As we have on more than one occasion described the Criterion, we need not here enter into particulars. Mr. Verity was not backward in describing any little points of failure or alteration made in the original arrangements during the six years since the opening of the building. For instance, in the dining-room on the ground floor, where light has to be obtained through the floor for the sculleries below, glass mosaic was at first used for the lights, but owing to the singular action of the indiarubber coverings to the wheels of the joint tables in continually passing over the lights, the pieces of the mosaic were picked out one by one, till only the cement filling remained. Ground glass panels have been substituted. Again, all the service as well as principal doors into the public departments were made of solid hard

woods. These used for service, where not immediately seen, might have been made in a less costly manner, seeing that the waiters generally having their hands full, invariably open the doors either with a sharp kick of the foot or thrust from the tray, so that in some cases all the solid mouldings have been worn off. The new building will provide a large American refreshment buffet and grill-room on the ground floor, and to the large hall of the Criterion on the second floor an addition equal to half its present length. On the first floor a suite of Masonic rooms will be arranged suitable for lodge and other meetings. Already the Criterion is the most important building of its kind in London, dining no less than two thousand as a minimum every day, sometimes over four thousand. When the new buildings are finished, the Criterion will be still more worthy of remark.

CHIPS.

A new school is about to be built by the Great Grimsby School Board for 750 children in the West Marsh district. It will be the second provided by the board, a former one for 1,100 having been built 18 months ago. The new school is from the designs of the board's architect, Mr. Charles Bell, of London and Grimsby.

The Richmond vestry received at their last meeting a report from Messrs. Russ and Minns, their engineers, as to the progress of the well now being sunk. They stated that the boring was now 130ft. into the chalk, but of this the last 20ft. was only 10 $\frac{1}{2}$ in. diameter, and that owing to the tough nature of the chalk they had not made the progress that was anticipated. It is now two years since the Southwark and Vauxhall Water Company cut off the supply, and in the interim the townspeople have been supplied from springs in the Petersham meadows.

The Merthyr Local Board have adopted the design of Mr. Dyne Steel, M.I.C.E., of Newport, for a new iron bridge at Troedyrhiw. The bridge will replace an old one of the same span, and will have a buckled platform, on which will be laid coal-tray, concrete, and road metal. The tender of Messrs. Tangye Brothers and Steel, of Newport, has been accepted for the execution of the work.

On Thursday week an inquiry was held at Cinderford, before Mr. J. Thorahill Harrison, C.E., Local Government Board inspector, respecting an application from the Westbury-on-Trent Sanitary Authority for sanction to borrow £1,800 for works of sewerage and water supply at East Dean. The proceedings were marked by several scenes, warm opposition being raised by some of the East Dean ratepayers to the scheme, the chief objections being the cost and the position of the outfall works.

A South Wales journal says that the last remains of the ruined College of St. Illtyd, at Llantwit Major, consisting of a triple archway leading out of a small covered area in a garden on the north side of the parish churchyard, have been reduced to a shapeless mass by the frost and snow of last week.

Mr. Brock, of London, has been commissioned to execute a statue of the late Lord Chief Justice Whitehead. The memorial will be erected in the Hall of the Four Courts at Dublin.

The Corporation of Preston have invited tenders for lighting the market-place and other open spaces in that town with the electric light.

A Local Board is to be formed for Hailsham, East Sussex.

A large railway hotel was opened last week near Brundish Station, between Yarmouth and Norwich. The architect of the house, which is known as the New White Horse Hotel, is Mr. A. J. Lacey, of Rampant Horse-street, Norwich, and the contractor Mr. John Withers, of Blofield.

A stained glass window to the memory of the Ashley family has been erected in Llaniton Church, near Oxford. The central light depicts the "Ascension." On the one side is Moses lifting up the serpent in the wilderness, and on the other the Saviour on the cross. The work has been executed by Messrs. Jones and Willis, of London.

The Hove town commissioners have instructed their surveyor (Mr. E. B. Ellice-Clark) to commence sewerage works at Hove-drive, and also to proceed with the new Medina groyne.

New Board schools have been erected in Surrey-road, Norwich, for the School Board of that city. Mr. J. H. Brown was the architect, and Mr. J. W. Lacey the contractor. Another school is to be built for the Norwich School Board in Crook's-place, from the designs of the same architect.

Plans have been received by the guardians of Middleton Union, Co. Cork, from Mr. A. Hill, of Cork, their architect, showing proposed reconstructions of and additions to the workhouse hospital. The expense is estimated at £1,000.

Building Intelligence.

EARLESTOWN, LANCASHIRE.—The new church of St. John the Baptist was consecrated on the 6th inst. by the Right Rev. Bishop Kelly, D.D., late of Newfoundland. The style adopted by the architect is "Transitional Early English." The church consists of chancel, terminating with a semi-octagonal apse, 38ft. x 25ft.; transept on each side of chancel, 21ft. x 16ft. 6in.; nave, 51ft. x 29ft.; and the two aisles, 51ft. x 12ft. each; the vestry, 15ft. x 12ft., is at the north-east angle of north aisle, the vault for heating apparatus being under the vestry. Only a portion of the church is at present built, and the temporary west wall of common red brickwork gives to that end of the building a very unsightly appearance. The church, as now finished, will seat 600 persons, but if the original designs are at some future time fully carried out, there will be accommodation for 1,000; 44ft. in length is left to be added to the nave and aisles. A tower is shown at north-west angle of north aisle, surmounted by four pinnacles with carved crockets. The stone dressings throughout are of Runcorn red sandstone; the walls externally are faced with Yorkshire parpoints, and internally with rubbed face white Stourton stone. The nave has a king-post roof, with moulded tie-beams and purlins; pendant-posts, with curved, sunk, and moulded spandrels, give an additional support to ends of the tie-beams; these posts rest on carved stone capitals, surmounting circular stone shafts, the whole supported by carved red stone corbels. The other roofs are constructed with framed and braced rafters, the whole being in red deal left from the plane, without stain or varnish. The chancel has a boarded ceiling, divided into panels by moulded ribs; the other roofs are plastered between the rafters. A carved block (stone) cornice supports the moulded wall-plate of chancel roof. The chancel stalls are of oak, with carved poppy-heads to stall-ends; the adults' and children's seats are of pitch-pine varnished. Gibbs's (Perkins' patent) high-pressure apparatus is used for the heating. The carving was executed by Mr. W. Stevens, of Liverpool. The church is glazed throughout with lead-lights and cathedral glass of different tints, with white and ruby margins. The building was completed in April last year, with the exception of part of the seating. The contractor for the church did not supply the seats. The church has been erected from designs furnished by Mr. C. T. Whitley, A.R.I.B.A., of Stretton; Mr. Joseph Pennington, of Earlestown, being the builder, and Mr. J. W. Randle the clerk of the works.

GREAT GRIMSBY.—A Fisher Lads' Institute is about to be built here on land given by Colonel Tomline. It will provide a much-needed want for the numerous boys engaged in the fishing trade, who now have no place to resort to when on shore. The new premises will provide a large swimming-bath, lecture-hall, coffee-room, library, and recreation-rooms, with agent's residence, &c., &c. Mr. Charles Bell, of London and Grimsby, is the architect, and the works are to be begun at once. The estimated outlay is £3,000.

METROPOLITAN BOARD OF WORKS.—On Friday the tender of Mr. C. Killingbeck, amounting to £4,850, for constructing new sewers in Priory-road and Kilburn-vale, Kilburn, was accepted. The following applications by local authorities were granted:—Loans: Kensington Vestry, £4,425 for sewer works, and £1,175 for erection of cart-sheds and stables; Poplar District Board, £25,500 for paving works; Mile-end Vestry, £2,000 towards an improvement in Oxford and Jamaica-streets; and overseers of Putney, £3,500 for purchasing and fitting up premises as parochial offices. Permissions to borrow: Kensington Vestry, £3,078, expense of rebuilding bridges, carrying Ladbroke-grove and Golborne-roads over the Great Western Railway; Plumstead District Board, £500 for paving works at Eltham; and Shoreditch Vestry, £12,000 for paving and improvement works. The board's seal was affixed to a schedule of land proposed to be taken compulsorily under the Whitecross-street scheme of the Artisans' Dwellings Acts of 1875 and 1877,

and an application was directed to be made to the Home Secretary to appoint an arbitrator as stipulated by the Acts. Petitions for provisional orders were sealed as to three other schemes under the same Acts in Great Peter-street, Westminster, Little Coram-street, St. Giles's and St. Pancras, and Well-street, Poplar.

STAMFORD.—The opening of the new infectious wards added to the Stamford and Rutland Infirmary took place on the 15th inst. The new wards are situated east of the older buildings, a space of from 40 to 50 yards intervening between them. Three blocks of two stories each afford on each floor accommodation for five patients and a nurse. The buildings are of the local stone of the district, oolitic of varying density. The quoins, jambs, and window-heads are of Casterton stone, the window-sills and plinths of Clipsham limestone. The walls are lined with glazed bricks throughout, built in as the work proceeded, and jointed in Parian cement. The whole arrangements have been carefully worked out by the architect, Mr. Browning, of Stamford.

Hobart Pasha has received instructions to establish docks and landing stages at Constantinople. The work will probably be carried out by a Newcastle firm.

The authorities of the National Gallery have at last placed a portion of the Turner bequest in a position in which it is likely to be of some use to the public.

Bowry's Almshouses, Bow-road, E., were last week sold by auction for demolition, the site having been sold by the trustees, with the sanction of the Charity Commissioners, to the churchwardens and overseers of the parish of Bromley St. Leonard, upon which to erect a vestry-hall. The new building will be from designs of Messrs. A. and C. Harston, which have been approved by the Local Government Board.

It will be seen, on reference to our advertisement columns, that the directors of the Industrial Dwellings Company require the services of an architect and surveyor, at a salary of £500 per annum. The duties of the appointment include the responsible supervision of the company's building operations. Mr. William Ward Lee, who has been honourably associated with the company since its formation in the year 1863, will become the consulting architect.

In reply to their advertisement, the Southport Highway Committee had 70 candidates for the situation of inspector of paving, &c. After going carefully over each letter and reference, Mr. Thomas Hewitt, paving inspector of Bolton, has been appointed. He was selected from seven, who were sent for to give personal explanation.

The preliminary drift way of the tunnel at West Noathly, on the line from East Grinstead to Lewes, was completed last week after seven months' continuous work. Mr. Fairbank is the contractor for the railway, which is making considerable progress.

It is proposed to erect a terrace of buildings at Trinity College, Dublin, in replacement of an old row of houses from the end of the library to the corner of Botany Bay-square. Mr. Deane, of Dublin, is the architect.

The Baptist chapel in North-street, Halstead, was reopened on Tuesday week, after renovation, from the designs of Mr. Charles Portwee, of Chelmsford. The cost has been £340. Mr. King is the builder.

The Local Board of Grauga, near Ulverston, have had plans prepared for the sewerage of the district by their surveyor. The estimated outlay upon the scheme is £3,000.

The Government of Uri propose to pull down the ancient chapel on Lake Lucerne, known as that of William Tell, and have, it is said, refused permission to the Lucerne Artistic Society to detach the paintings on the walls, that they may be placed in the museum at Lucerne.

Mr. D. J. Humphries, late borough surveyor of Cheltenham, who carried out the present plan of sewerage irrigation for that town, died on Tuesday week in his 64th year.

A Local Government Board inquiry was held at Beccles on Wednesday week, before Col. Pensonby Cox, R.E., with reference to an application from the Town Council for sanction to borrow a further sum of £2,000 (making a total of £3,000) borrowed for works of sewerage. There was no opposition to the application.

The States of Jersey on Friday last invited Mr. Philip le Sneur, the States' architect, to send in his resignation on the ground of failing health. It was referred to a committee to consider the amount of annuity to be offered in consideration of Mr. le Sneur's long services.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post-free 2d. Office: 31, Tavistock-street, Covent-Garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 60s. 40c. gold); for France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted, some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

A. B. O. (The fact of the board having inadvertently affixed their seal to the plans with the dimension in figures fixing the frontage line cannot be held to make the plans unalterable in the face of any rule or precedent defining the line of building. The plans were signed probably in ignorance, and if the houses are begun the costs certainly should fall upon the board.)—H. H. H. (There is no dictionary of terms in French and English that we know of appertaining to architecture.)—"PERSPECTIVE." (The perspective points can be obtained only by the means laid down in treatises on perspective, and we can recommend Burchett's "Perspective.") The central line is an instrument lately introduced for facilitating the drawing of vanishing lines, and numerous explanations of its use have appeared in the *BUILDING NEWS*. The best rule to remember as regards vanishing points and lines is that all planes of the original object or building have their vanishing lines and points, and each of these lines is supposed to be made on the picture by a plane passing through observer's eye parallel to its original, till it meets the picture.)—TRY. (Need any honest person ask such a question?)—W. G. GASS. (W. M. Shirreff, 13, Palmerston-buildings, London, E.C.)

Correspondence.

ST. ALBAN'S CATHEDRAL.

To the Editor of the *BUILDING NEWS*.

SIR,—When I read my paper on St. Alban's before the Society of Antiquaries, on November 28th last, I exhibited a rough drawing to show my views, both as to the pitch of the original roof of the nave, and also as to its design. Messrs. G. G. Scott and J. O. Scott, the architects of St. Alban's, forthwith made a drawing, in order to show how inaccurate I had been. Mr. J. O. Scott at the same time prepared a report in answer to me, which was read at a meeting of the St. Alban's Architectural Society, on the 17th December, with a prefatory remark from the rector, as chairman, that it had "had considerable influence over the decision of the Faculty Committee in the course they had adopted with regard to the roof of the nave." It contradicted very positively the arguments which I had adduced, and was based on what was asserted to be an accurate measurement as contrasted with my hasty conclusions and incorrect drawing. In that report I find the following statement, made by Mr. J. O.

Scott, to which I wish now to call particular attention. He says:—"Doubtless, if Mr. Street is right in his conclusions, the only reasonable course open to the committee would be to abandon the proposed high-pitched roof." The alternative being "a bold act of destructive restoration," in which "I, for one, could never consent to take part." My conclusion was that there had never been a steep-pitched roof, with parapets on the nave of St. Alban's, and that Mr. Scott's scheme would give us something the like of which had never before existed there.

As long as Mr. Scott's impeachment of my accuracy could not be answered, I felt it to be impossible to hint at any possibility of inaccuracy on his part. But the careful drawing which Mr. Neale has made and published of the west wall of the tower is drawn in so minute a fashion that it is well-nigh impossible that it can be seriously incorrect in any single particular, and as it proves that my drawing was a singularly exact one, being nowhere more than about three inches out of the real line, there can be but one conclusion, I should suppose, as to the necessary results. Mr. Scott's own drawing of the roof lines has none of the evidences of careful examination and detail of the old roof line which Mr. Neale's shows, and indeed it absolutely ignores—as if they did not exist—the most important marks that remain.

If there is still any disposition on Mr. Scott's part to contest my own and Mr. Neale's accuracy, I would suggest that the best plan would be to exhibit for a short time at the Society of Antiquaries Mr. Neale's drawing, Messrs. Scott's drawing, and a large photograph, made for the purpose, of the wall itself. The facts will then be clear and indisputable, and Mr. J. O. Scott has already announced what his conclusion will be if they prove me to be right!—I am, &c., GEORGE EDMUND STREET.

14, Cavendish-place, W., Jan. 22, 1879.

ROOF OF ST. ALBAN'S ABBEY.

SIR,—Since my last rather lengthy communication was written, Mr. J. O. Scott's section has appeared in the *BUILDING NEWS*, and Mr. Neale's elsewhere. Until the latter came out we were still practically in the dark as to the lines which Mr. Scott had really laid down, whether of the supposed old roofs or of the proposed new one. And although he has shown Mr. Scott to be wrong in his conclusions, it is some satisfaction to find, after all that has passed, that Mr. Scott's lines were not impracticable and unreasonable, as from his section and previous explanations they appeared to be. That section was manifestly an impossible one, and must have been, from some cause or other, quite incorrectly given (see p. 23, *BUILDING NEWS*)—the top of the original Norman wall, as indicated at D, being shown 18in. below the bottom of corbel-table, whilst the supposed line of the original Norman roof would intersect the face-line of wall at 18in. or 2ft. above it; and, on the contrary, the supposed lowered roof would correspond very nearly with the line at D. Mr. Neale, however, shows that Mr. Scott's line really started from the top of the corbel-table, where Mr. Street and myself had placed it in our sections exhibited at the Society of Antiquaries, only that Mr. Scott placed the apex of his later lowered roof at the point indicated by H (see *Builder*, p. 69), which has correctly been fixed on by us as the apex of the original roof, and which Mr. Neale finds conclusively to be so. Whether Mr. Scott's radically new line he carried or not, he will at any rate not regret now that the investigation, made primarily at the instigation of the Society of Antiquaries, has resulted in Mr. Neale's masterly production, which has placed on record the architectural evidences of the case in such a clear and simple manner.—I am, &c., WILLIAM WHITE, F.S.A.

CENTRAL AREA CHURCHES.

SIR,—I read with great interest Mr. James Cubitt's article in your issue of 13th December last. Anything the designer of Union Chapel, Islington, has to say on the subject must always be instructive, as he has had the advantage of carrying out his ideas thereon in practice. As, in referring to the sketch-design I made for Truro Cathedral, he credits me with "taking a hint from Sienna," let me remark in

passing, I am rather ashamed to confess I did not know, till reading his letter, that the Italian cathedral had a central hexagon; however, on looking it up, I find it is so. The model I had in my mind was nearer home—the octagon at Ely. Principally for the reasons Mr. Cubitt states I adopted the hexagon instead of the octagon form in plan, though externally—as he remarks—it is not so easily treated. Had the site at Truro permitted longer transepts—say even to the extent of one bay only—the result would, I think, have been much more satisfactory for the general grouping. The nave might also with advantage be made wider than it is in the sketch, but I'm afraid the triple-roofed arrangement, suggested by Mr. Cubitt, would hardly compensate for the sacrifice it would involve—as at Bristol—of one of our most beautiful features, the clerestory, and I even doubt if a three-gabled narthex, such as at Peterborough, though magnificent in itself, would, without massive towers or spires, be able to hold its own against the bulk of the central lantern.

Doubtless both cathedrals and churches designed on the central area principle are more suitable to the greater congregational requirements of the present day than the long-drawn nave and aisles of the middle ages. I was glad, therefore, to see Mr. Carpenter had adopted it in his design for Manchester, and only hope he may soon have an opportunity of carrying out such a magnificent scheme, though perhaps Mr. Cubitt is right in saying the double-aisled nave is hardly the most suitable for the Anglican service.

It has often struck me as surprising that the octagon of Ely once designed, it did not lead the way to a further development of a central feature capable of so much beauty. Alan of Walsingham stands alone in this respect among all our English designers, none having had either the courage or the skill to follow up the example he left them, and yet he was apparently on the road to a Gothic dome—a feature we do not possess either in the ancient or modern English work of the style. It has often been quoted, as a reproach against Gothic, that what Wren and others have done in this way in Classic, has never been equalled or even approached in that style. Perhaps at the present time when, as a recent writer says, "The mediæval feeling is rarely the moving power of vigorous and thoughtful design," it may be too much to expect to see it accomplished. Still, as a covering for the central area of a church, no grander feature has yet been devised.

The tendency of our architects has rather been to solve the problem by increasing the width of the nave, as in some of Mr. Street's churches, and more recently in the striking churches, by Mr. Pearson, at Kilburn and Red Lion-square, where the side aisles are reduced to the dimensions of passages. No one can deny the success of these works, which present many features of planning worthy of attention. Only this is working out the subject on the old lines, it would be interesting to see what artists of such power would make of a large central area, where the old traditional forms could not be had—a site, for example, like St. Stephen's, Walbrook, where Wren has given us one of his most beautiful interiors.

Though perhaps irrelevant to the subject, Mr. Cubitt also discusses the question—argued some time ago in your columns—of the harmony of Gothic architecture with high class painting and sculpture, and says we must choose between "high art decoration and tracery decoration"—that is, Late Gothic and high art "do not go together." It seems to me it all depends on the excellence of the Gothic. High art will never agree with poor architecture, as in like manner it will never be out of place with really good artistic work, whether it be Late or Early Gothic—just as it is with Classic. As Stevens used to say, there is but "one art," and so long as the painting, the sculpture, and the architecture be really high class, designed and executed by artists to suit the purpose for which they are to be combined, there need be no fear about the result. But the designers must be artists—that is the first condition of harmony; if they are not and the work is, in consequence, poor, then they may call it anything they like—Gothic or Classic, Late or Early, it will not be art.—I am, &c., J. M. BRYDON.

SURVEYORS' FEES — QUALIFIED SURVEYORS v. QUACK MEASURERS AND ARCHITECTS.

SIR,—I quite agree with the strictures passed by an "Old Builder," and shall feel obliged by your inserting the following for the purpose of ventilating this subject.

Some few years since an old client instructed me to send him estimate and specification for repairing and redecorating his house. In due course this was done—the amount of my estimate being £612. After an interval of a few days client sent for me, and said he was quite satisfied with estimate, and a date was named for commencing the work. Some few days after he again sent for me, and said he intended to employ an architect, and asked me had I any objection to work under one, at the same time showing me architect's card, by which I found he was able to add F.R.I.B.A. after his name and profession. As a matter of course I expressed my willingness to place myself under his control. Consequently, in due course, the works were commenced, during which time client and architect ordered several extra works to be done. It therefore occurred to me one day at a meeting of client, architect, and self on the works, to call their attention to these extra works which were now accumulating very fast, and suggest to them to allow me to send in a statement of extra work up to date, and estimates for the other extra work then just ordered, for the purpose of avoiding any dispute as to cost at close of works. My client's reply was—"Mr. D., you have worked for me many years, and I have full confidence in your charges, and when the works are completed myself, my architect, and yourself will go over the account together, and settle the same amicably ourselves." Consequently, feeling secure on this promise, I proceeded with and in due course completed the works to the full satisfaction of client and architect, after which came the tug of war. I made out my account, and sent it to architect, the total of contract and extra amounting to about £1,117. After much delay the architect writes me that, having been over my account, he could not make anything of it, and he had recommended his client to have the work measured and valued, and that he had appointed a certain day for his surveyors to meet me or my representative on the works for the purpose of measuring up. Consequently, on the day named, my foreman attended and met the two men, and they were engaged about a fortnight over the work. After this another month elapsed, and, after several requests for a certificate, one day I received a lithographed price bill of quantities of about 70 pages, with note inclosed, informing me that Mr. Architect's surveyor had carefully measured and valued the work, the result of which was they had valued the whole of works done (contract and extra) at about £670, and, if I was satisfied with same, Mr. Architect was prepared to grant me a certificate for that amount.

I examined the bill of quantities for an elucidation of the great difference in amount, and was not long before I discovered that measurements and prices were most shamefully wrong—even on the first page alone there were many pounds short in prices and quantities.

I called upon the architect, and showed him several of the most glaring errors, which he pretended not to see, and finally closed the interview by informing me that he had every confidence in his surveyors, and would not allow me to question their veracity. I thereupon left him the quantities, and came away. Some few days or weeks after he again returned me the quantities, and said his surveyor had corrected a few errors, and I could have a certificate for about £700 in full settlement of my account. Of course I could not accept so ridiculous a sum, and wrote him to that effect. Several weeks more elapsed, and I could not get any further settlement from the architect. I then wrote the client, informing him of the injustice under which I was suffering, and reminded him of his former promise for the meeting to take place and settle the matter. Client wrote me, saying that he had been advised by his architect my account was not correct, and that he had left the matter entirely in the hands of the architect. After further delay I again wrote the client asking

him to reconsider his determination, when I received a note from architect to meet him and the client at latter's house, which I attended, and pointed out again several mistakes and omissions in the quantities, which the architect would not admit and the client would not see. So the meeting broke up on the understanding that architect would write me respecting the result of our conference.

After a few days the architect writes me to say he is willing to give me a certificate for £800 in full settlement of my claim. This I promptly yet respectfully refused, and after another delay he again wrote, offering £900, which I again refused. After further correspondence, the architect again writes me, saying he would, as an ultimatum, give certificate for £1,000. This I promptly refused, and not being able to obtain any further advance from the architect, and feeling entirely disheartened and disgusted with the treatment I had received, I resolved upon placing the matter in the hands of my solicitors, and instructed them to proceed with an action for the recovery of the full amount of my claim. To my surprise, the morning following that on which my solicitors had given notice of action, client called upon me at my office, entreating me to stop the action, and to meet him at his residence next morning to settle accounts, where I attended in due course, when he told me how shamefully he had been treated by being charged £50 for that precious bill of quantities, and about £200 for architect's services. I reminded him it was all his own fault in not keeping to his original promise. In reply, he asked me to pay the £50 for quantities, which I refused. Yet, after further begging hard for some reduction, I considered he had fallen into evil hands, and so consented to take off the odd £17, and thus made a settlement at £1,100, after which I informed client that I must respectfully decline to have any further transactions with him. I assure you I have been extremely careful since not to place my reputation or property too readily in the hands of any architect or surveyor who may wish to ruin me.—I am, &c.,

J. W. DUFFIELD.

Queen's-gate Works, Kensington Gore, S.W.

QUACK SURVEYORS.

SIR,—Your correspondent "Provincial," in assuming that my remarks in your issue of the 10th inst. did not apply to "surveyors," is correct. The scandals alluded to are usually the work of men engaged by their clients as "architects"—the client, in nearly all cases, being under the impression that the usual 5 per cent. commission is the total remuneration his architect receives for his services of every kind; whereas I can show that the architect frequently extracts from his client from 10 to 12 per cent. additional for "quantities," "copies," and "measuring."

I can assure your engineering correspondent of 7, Westminster-chambers, clients are so green as not to know of the existence of the charge for quantities, and it is only a few weeks ago I read a letter signed by a Westminster firm of engineers—members of the same society as your correspondent—in answer to inquiries from a public board, to the effect "that although they would charge a commission for quantities, it would make no difference to the board, inasmuch as the contractor paid them for that work." In that case ten out of twelve members of the board were "green," the other two, being old hands at the business, exercised their fair influence, the result being the appointment of an independent surveyor.

In my experience, which is large, I maintain that the work of a bona-fide surveyor is well worth the fees or commission such men charge, and that they never resort to fraudulent tricks to swell their bill. Their work is so well done that it is open to the light of day; they furnish every detail of their dimensions when required, and are always ready to defend the accuracy of their work, or accept the responsibility if inaccurate. While, on the other side, the "quack" who is usually the architect as well as surveyor, frequently charges a higher commission, and not unfrequently manages to issue two or three sets of quantities for the same job, charging commission each time, although the

repetition is the result of his own ignorance rather than the fault of the client, who has to pay. The quackery of these men could easily be discovered by a sight of their dimension books, but they take care not to expose them to any eye but their own, and the builder is in the same happy state of ignorance as the client until the work approaches completion. If an ignorant man he finds his place in the Bankruptcy Court; or, if he knows his business, he finds the necessity for submitting a large bill of "extras," which oftener means "deficient quantities," and I candidly admit in some cases he discovers the quantities to be largely in excess for his benefit.

Perhaps the most important point in this discussion has not yet been mooted by any of your correspondents. It is this:

In many, if not most, cases in which the architect issues a bill of quantities, such work is not even done by himself, but by casually engaged clerks in receipt of about 40s. to 60s. per week. These men are usually inefficient joiners, masons, or bricksetters, who, not being able to keep in constant employment at their own trade, having the advantage of fairly good address, obtain occasional employment as clerks of works or office clerks. They thus pick up a smattering knowledge of measuring, and in their ignorance, and in want of a situation, they represent themselves as quantity surveyors; their employer, the architect, pays probably a fortnight's wages, say £5, and after endorsing the bill with his signature charges one, three, or five hundred pounds as he sees fit. His client pays it, without knowing, and has no voice in the matter. Needy assistants of this kind are not always proof against the bribe of the "lowest" but most intimate of his building friends frequenting the office, it being well known that Brown or Jones takes out all the quantities in So-and-so's office. Poor fellow, he only gets two guineas a week; who can wonder at his accepting the generous offer of £50 from his friend Black, the builder? All he is expected to do for it is to add on to the quantities a few rods of brickwork and other things in proportion.

I feel unable to fathom the case named by your "Constant Reader," who does not appear to know that it is almost impossible for a builder to obtain a contract in which he is allowed to make his own account—he is usually bound to accept the architect's certificate of a final account; and that it seldom occurs that the contractor has any voice in the appointment of the surveyor. AN OLD BUILDER.

ARCHITECTS AND SURVEYORS.

SIR,—Amongst the mass of correspondence which has taken place from time to time on the relation between architects and surveyors I have not seen it clearly stated what are the position and duties of the quantity surveyor. Most of the writers appear to treat him simply as a man who performs a portion of the work of the architect. A practice of nearly 20 years, and an intimate professional acquaintance with some of the most eminent of the London surveyors, have convinced me that the two professions are quite distinct, and that one cannot be legitimately practised on the same occasion as the other. A surveyor is properly a builder's man, and not an architect's. It is his duty to take out the quantities of the several descriptions of work from the drawings in the manner that builders require for inserting their prices, and to arrange them in such a way that important items, depending on the difficulties of the work or on the state of the market, may be placed prominently before the parties who are expected to tender, as they are seldom allowed sufficient time to go into the matter for themselves. In my experience this is what architects and amateur surveyors seldom attempt, and when they do they almost invariably give prominence to items which, although important, perhaps, as architectural features, are often of minor consideration as regards expense. Hence the honest builder has no love for quantities prepared by inexperienced persons. Dishonest ones, however, often find in these imperfect quantities an engine of immense power in controlling the architect and placing him under his thumb. If the quantities be in excess the fact is never mentioned, and in a

large job it is only the builder, who has to order his materials, that will find it out: the architect has no means of doing so without an amount of labour that few would be willing to undertake on the chance of discovering an error.

Again, the surveyor is not inaptly termed "a builder's attorney," and a bill of quantities may be compared to a deed of settlement or conveyance, in which every sentence must be framed to admit of only one meaning—viz., that which conveys the intentions of the parties; but with bills of quantities the difficulty of expression is greater, owing to the variety of description to be found in builders' work, and courts of law will not permit of extraneous evidence to clear up obscure meanings in a contract.

In contentious cases arising out of builders' contracts it is the surveyor who must prepare the case for counsel and work up the evidence, as few solicitors are sufficiently acquainted with the technicalities of building to do it themselves.

The duties of a surveyor require a long and special training of a kind that is incompatible with that necessary to make an architect. Errors in quantities for large works can only be avoided where the parties engaged have been trained to the duties from their early boyhood. Those who take up the profession later in life have not the routine of the duties sufficiently impressed on their minds; consequently, in large jobs, they get bewildered before they are half through the work, and errors creep in which somehow or other, on whatever side they be, come out of the employer's pocket.

A noticeable point in most of the correspondence which has lately taken place on the matter of quantities is the percentage charged by the quack surveyors. Why, sir, it is almost double that which the most eminent surveyors in London charge for their work. It appears to me that the system in vogue 20 years ago was the best of all, and the most satisfactory to the employer. The architect prepared his drawings and specification, and the builder was bound to carry out the work for the amount of his tender, regardless of what was taken in the quantities by the surveyor, whom the builder had himself appointed. By an estimate of a simple description, which every architect should be competent to prepare, he would be enabled to advise his employer on the reasonableness of the tender submitted by the builder. This dabbling in bills of quantities by architects has been the cause of more claims for extras and other annoyances to employers than anything I know of.—I am, &c., J. S.

ARCHITECT OR SURVEYOR.

SIR,—Under the above heading instances of collusion between the builder and the surveyor have been pointed out by "Old Builder" and "Constant Reader." I would point out how this is conducted by the possibly increasing practice of the architect entrusting the taking out of quantities, and especially the measuring up of the works at their completion, to an independent surveyor.

The client employs the architect, and he relies upon the architect for his assurance that the final measurements are correct, and that the final bill is right.

So long as the architect supervises these he can confidently assure his client of their accuracy, but immediately that he deposes these works to an independent surveyor all control passes from the architect, and any "collusion" between the contractor and the surveyor is altogether unknown to the architect, who indeed is precluded from questioning the surveyor's bill when it is presented.

How indeed an architect can certify the correctness of an account, in the preparation of which he has had no part, and over which he has had no supervision, I fail to see.—I am, &c.,

ARCHITECT.

CONTRACT SCHEDULE OF PRICES.

SIR,—The schedule of prices upon which estimates are based are equally applicable to additions or "extras" to and "omissions" from contracts, I have always understood. Will some of your obliging correspondents have the goodness to inform me if there are any special cases, and what they are, when an exception to the rule is justifiable, and regular in its adoption? As in an extensive contract for a public work,

with which I am familiar, a large quantity of lias concrete was provided for in the bills of quantities—viz., 4,317 yards cube, at 6s. per yard (at which price the item was duly credited the clients as "omissions")—but in the "extra" works bill, as per measurement, 16,441 yards cube was charged at 8s. per yard. The difference in the price, as will be seen, puts £1,644 into the contractor's treasury. The quantity surveyor measured, and made out the amount, the contractors approved of his liberal views, and the architect certified the same, and so the transaction was completed! I make no further comment on it, than that it appeared to me to be an extraordinary thing that in the "omissions" or credits the schedule should be recognised and adhered to, whilst in the debits or "extra" works, its existence should be ignored! What service can a schedule be, if it does not govern and control the rates at which both "extras" and "omissions" are valued?

I should feel very grateful to any one who can show some valid grounds upon which the divergence from such schedule is allowable and permitted.—I am, &c., CONSTANT READER.

CLERICAL DRESS IN 1750.

SIR,—The figure described by Mr. Harry Hems as that of a clergyman in 1750 I should imagine would be more accurately described by him as that of some schoolboy like those of St. Margaret's and the Grey Coat Hospitals—familiar to us in Westminster, or the "Blues" of the City, or one maintained by the alms of the good folk of Pinhoe, as his place over the offering-box suggests. Savage, in 1735, thus describes the dress of the period in the "Progress of a Divine":—

Let testimonials then his worth disclose,
He gains a cassock, beaver, and a rose.—I, 19.

On obtaining a curacy he adds, without authority:—

A swelling, rustling, glossy searf. [of a D.D.]

(See for the long buttoned cassock my annotated "Canons of 1604") (J. Parker, 1874.) In 1753, Archdeacon Sharp, in his visitation charge, mentions as the dress "worn on every occasion abroad, and even upon journeys such badges as the band, hat-band, or short cassock," which falls in with one of the directions in the canons, "uti ne in publicum nisi promissis vestibus induti prodeant," which "promissæ vestes" are interpreted in a marginal note by cassocks, and in the English version of the canon by a paraphrase which implies a liberty of wearing them short, "in their doublet or hose without coats or cassocks." (My edition, p. 150.) Addison, in the *Spectator*, 1714, No. 609, mentions a clergyman "equipped with a gown and cassock for his public appearance." Fielding's Parson Adams, in 1742, is repeatedly introduced as wearing the cassock. The clergy, about the year 1820, had as a body entirely neglected the use of the short cassock in public, and the great majority even the clerical hat and rose, which are now worn by bishops, deans, and archdeacons. The short cassock differs from the long kind in having no collar or sleeves, as it was worn under the coat, and extended only about 2in. below the knees. In the beginning of this century there were cassocks for riding, and others for walking. They had a broad band or sash round the waist. The beaver was triangular in shape, often known as a "wind-cutter" to "Old Westminsters" when adorning a head-master in the present century. It has been changed into a round form with a low crown and a broad brim tied up behind. The present broad ribbon has superseded the hatband—a roll of black silk stuffed with wool—which was used to puff out the interstices or folds of the triangular hat. To it Dryden alludes. The pair of bands are so designated by Bishop Taylor; and Addison, Ben Jonson, Swift, Pope, and Crabbe call it the band. It is the "collare" of the Oxford Statutes, and superseded the Jacobean ruff. In a satirical print of 1814, which lies before me now, the "master parson" is dressed in the short cassock and sash, a full-sleeved gown and scarf, a beaver, and rose wig, and bands; the "journeyman" has a beaver and ribbon (bands), gown, and scarf, a buttoned doublet, and knee-breeches, with shoes tied with strings. Those of his companion have buckles and watertight tongue.—I am, &c.,

MACKENZIE E. C. WALCOTT.

PENMAENMAWR OR BLUE WELSH STONE

SIR,—Referring to Mr. Allison's (borough surveyor of Bradford) letter to you headed "Penmaenmawr or Blue Welsh Stone," appearing in your issue of the 17th inst., we beg to correct any wrong impression that this title may convey as to the name "Penmaenmawr," when applied to setts, being now synonymous with "blue Welsh stone."

The first quarries opened here were no doubt in the blue stone, and very large quantities of this material must have been sent away, as is proved by their great extent, but our quarries, though at Penmaenmawr, are not in the blue stone at all. The colour of our granite is grey, the grain is coarse, and calculated to combine in a remarkable degree durability with an excellent and lasting working surface so necessary for a heavy and busy traffic.

We believe our granite is especially adapted for meeting the requirements of the general traffic of a large town or city, or the concentrated traffic between the rails of a tramway, so that we feel sure Mr. Allison will be ready to do us the justice of admitting that when he referred to "Penmaenmawr or blue Welsh stone" he did not apply his remarks to our grey granite.—We are, &c.,

DARBISHIRES AND CO.

Penmaenmawr, January 22nd, 1879.

THE BELLS OF ST. MICHAEL'S.

SIR,—I have just received my copy of this week's BUILDING NEWS. I am sure that many of your readers besides myself would like to know how the bells of the Church of St. Michael and All Angels, Bedford-park Estate, are to be rung, and where the ringers are to stand. From the drawings I make out that there are five bells (*en passant* I would mention the great weight of five bells carried on a roof), four in the bottom story and one in the top. Now, to ring a bell properly the clear space in front, behind, and above it must at least be equal to its own height—that is, the bell must be able to turn completely round its own axis. It seems to me impossible for these bells to do this. Perhaps Mr. Shaw will explain to us how he intends the bells to be used. I hope he does not intend them to be simply used with a carillon machine. Those carillon machines are almost stamping out the noble art of campanology.—I am, &c., JUNIOR.

THE NEW LAW COURTS.

SIR,—In your impression of Friday, January 17th, you give a description of the work at the east block of the New Law Courts, in which you state the clock-case to be by Mr. Benson. This is no error, as it was made and fixed by us to the design and order of G. E. Street, Esq., R.A., and so far as we know Mr. Benson has nothing to do with it. There is also an error as to the door furniture, which you say is by Mr. Lever. We are the makers of it.—We are, &c., THOMAS POTTER AND SONS.

South Molton-street, London, W., Jan. 18.

At a general assembly of the Royal Academy of Arts, held on Wednesday evening, Mr. Valentine C. Prinsep, Mr. S. Luke Fildes, and Mr. J. M'Whirter, painters, were elected associates.

The London School Board, on Wednesday, rearranged the staff of the architect's department, placing on the permanent list five draughtsmen, a tracer, a junior writing clerk, and an office youth. The salaries of several of these officers were increased.

Plans for new offices for the Portsea Island Board of Guardians have been prepared for that authority by Mr. Houghton, their architect, and will be carried out subject to the sanction being obtained of the Local Government Board. The estimated cost is £3,650.

A bookkeeper and collector, named John Waring, has been committed for trial at Liverpool, charged with having embezzled about £2,000 belonging to his employer, Mr. Westmoreland, a builder, of that town.

A new Wesleyan chapel is about to be built at Rotherfield, near Tunbridge Wells, to accommodate 200 persons, at an estimated cost of £600.

Plans have been prepared by Mr. Anderson, architect, of Edinburgh, for the rebuilding of Mount Stuart House on the Firth of Clyde for the Marquis of Bute, on the former site, leaving the wings as they were before the fire in December, 1877. The new design contemplates a large addition to the main building, which will comprise a magnificent central hall, with suites of rooms on either side. Lord Bute has approved the plans, and tenders are about to be invited for the work.

The parish church of Heallan, near Denbigh, has been restored, and will be reopened on Tuesday next. Last week one of the glaziers at work on the building, a man named Joseph Davies, of Chester, fell headlong through the window owing to the shifting of the ladder, and was killed. At the inquest it was deposed that the deceased had set his ladder on a board laid across the pews, the upper end forking a mullion.

The Brighton Town Council have appointed Mr. Benjamin Lomax, C.E., of that town, curator of the museum, free library and pictures gallery.

Intercommunication.

QUESTIONS.

[5645].—**Stability of Walls.**—Will any of your readers give me a practical rule for calculating the required strength and dimensions of retaining walls, both for sloping and horizontal earthwork, also walls holding back water in reservoirs?—C. E.

[5646].—**Condensation on Walls.**—Would some reader kindly advise me in the following case?—The walls of a bedroom are painted four coats oil colour, the result being that during hot weather moisture condenses on them and makes everything in the room damp. Is there any way of curing this condensation and consequent dampness except by taking off the paint and fresh papering? I may add that sizing and papering were advised, also ventilation by means of the window and door. These were tried, but with no better result.—C. C.

[5647].—**Glass.**—Would any reader state if the glass used for gas globes, commonly called white globes, can be got in flat sheets?—LIGHT.

[5648].—**Timber Houses at Lisieux.**—In passing through Normandy lately I noticed at Lisieux two very fine houses of timber in the Grand-rue (near the cathedral), but had not time to sketch them. As these old houses are fast disappearing would any of your correspondents who are fortunate enough to have drawn them publish in your journal for the general good? P.S.—These two houses stand together, and one overhangs very much.—J. G. ELGOOD.

[5649].—**Country Public-houses.**—1. Is there any work published which gives examples of some of the fine old country public-houses, half-timbered or otherwise, such as those always associated with coaching days? 2. Will some of your readers kindly name the whereabouts of some such public-house within, say, a 30-mile radius of Trent Junction, which would repay a visit to any one interested in this study?—J. W. W.

[5650].—**Preparing Wood Blocks.**—Can any correspondent kindly enlighten me as to the mode of preparing the surface of the wood block preparatory to drawing upon it for wood engraving? I learnt it once, but have forgotten it.—J. S.

[5651].—**The Use of Statuary Marble in Out-door Work.**—An Exeter architect has shown me a letter, wherein a London marble merchant, advocating the use of statuary marble for out-door purposes, gives the assurance that it will resist the atmospheric influences of Devonshire fully as well as it does those of other counties in England. Surely this is very ambiguous. It would be interesting to know in what counties statuary marble will stand when exposed to the ordinary changes of the weather. Silician and vein marbles withstand the changes of our trying climate well; but, so far as I recollect, I know no instance of pure statuary being used successfully.—HARRY HEMS.

[5652].—**Cast of Carvings.**—I wish to take impressions of some stone and wood carving, and to take plaster casts from the same. Can any of your numerous correspondents kindly inform me of the best method to do so?—J. W.

[5653].—**Castings Plaster of Paris with Gelatine Moulds.**—Would any of your kind readers inform me if there is any chemical used in hardening the surface of a gelatine mould, and, if so, what? I use the best Russian glue, and have rubbed several stuffs on the surface of it to harden it, but without success, this climate being so warm that after a few casts are taken from the mould it becomes quite flabby and soft, and loses its sharpness. Perhaps some of my fellow-plasterers in good old England will oblige me with the above information—also if there is a better kind of glue used; and I will only be too happy to supply any information about the Colonies.—AUSTRALIA.

[5654].—**Red Quarry Floor.**—I have recently laid down a 9in. red quarry floor, bedded in mortar, and grouted in Roman cement. The quarries, although good in colour, were rather uneven, and the bricklayer rubbed them level at the joints. They have now gone a bad colour in patches. Can any of your numerous readers kindly explain the cause of this, and say what can be done to remedy it and make them their proper colour?—A SUBSCRIBER.

[5655].—**Surveyors.**—I shall feel obliged if any of your readers who may have had experience in such matters will kindly give their opinion on the following subject:—In the case of two surveyors looking at one set of quantities, one of whom is appointed by the proprietor of the work, and the other elected by the builders to watch their interests, (a) is the surveyor for the proprietor not bound to do the work completely for his client, at the same time giving every facility to the builder's surveyor for checking him as he proceeds; (b) and is it not out of the power of the former to insist on the latter doing anything beyond exercising such a careful supervision as he may consider necessary for the protection of those whom he represents?—SURVEYOR.

[5656].—**Esthetics.**—Will any reader kindly give me a list of works on esthetics, ancient and modern, English and foreign?—C. F. W.

[5657].—**Slaughter-houses.**—Can any reader give me information regarding slaughter-houses, or recommend some good work on the subject?—J. J.

[5658].—**Lime.**—Could you or some of your experienced readers inform me what is the quantity of lime required for a cubic yard of rubble masonry; also for a superficial yard of stone pitching, 8in. deep and 1 of lime? I am charged with what appears to me an enormous quantity of lime for the work done. I am about to build a brick garden wall. What quantity of lime should a cubic yard take?—E. C. S.

[5659].—**Brick Kiln.**—I want to know the simplest way to convert a furnace kiln, with smoke flues through the crown, into one that will consume its own smoke, or at least very much reduce the nuisance?—W.

REPLIES.

[5631].—**Sketching.**—As supplement to the information given by "O. E. S." let me add that Lyng has a fine W. tower and benches of 15th-century work, but North Curry and Stoke St. Gregory are of greater interest. Both are cross churches with central octagonal towers. A small monument with inscription at Athelney has an historical interest only. The ruined church on a mound is not worth a visit. Othry has an octagonal tower. From Langport Curry Sivel and Isle Abbotts should be visited; the latter, one of the most interesting churches of the district, having a beautiful Early Geometric chancel and a Norman font, in addition to very perfect specimens of the Tudor tower, benches, &c., which are so common in the neighbourhood. In addition to those mentioned by "O. E. S." there are octagonal towers at Ichester, Piddimore Milton, Weston Bamfylde, Barton St. David's and Douling, and also at Bishop's Hull and Pitminster, near Taunton. They form a feature in Western Somerset, and are worth collective study. The chief feature, however, throughout the county is undoubtedly the towers and other 15th-century work, which is not of such value to the architectural student as the earlier and robust work of the larger buildings of Lincolnshire and Northamptonshire; nor do I think the churches present such studies of picturesque effect and arrangement as the smaller ones of Sussex.—A. F.

[5633].—**Concrete Columns.**—I should recommend Portland cement above any other material for filling in columns under water.—G. H. G.

[5639].—**Quarries.**—Can be procured from any glass works that still manufacture crown glass, or from a merchant (Dawbarn and Co., 3, Temple-street, Liverpool). The sizes vary considerably. Some tables can be cut up to about 2in. from the "bull's-eye," others not nearer than 4in., leaving quarries from about 5in. x 5in. up to 9in. x 9in. A tinted surface can be obtained on plaster by mixing a finely-ground colouring pigment in a dry state with Parian cement. This can be applied in the usual way as a thin finishing coat on a ground of Portland cement, which, after being well trowelled, presents a polished, non-absorbent, washable surface. In imitation marbles and scagliola the colours are inserted in a semi-fluid state on the surface before the facing is put on. In some cases silk thread is used as the medium, the threads being drawn through the facing cement, leaving the colours behind. A backing of canvas or cement may be put on of any thickness required. It is afterwards polished by friction.—C. W.

[5640].—**Jointing Drains.**—Some engineers object to clay jointing, but I have never heard any good reason for so doing. Like "B," I have always preferred clay as a luting. If clay puddle is good for lining trenches, surely it is good for jointing pipes, as being more yielding. Cement cracks if used alone, and pipes laid with cement pipes are never proof. The asphalt joint is no doubt the best.—G. H. G.

[5641].—**Flues.**—A 9in. square flue is now recognised as amply large enough for ordinary building, although in the Chimney Sweeps Act the old size is adhered to. The general practice of architects is to make square or circular flues. The remarks in the "Commonplace Column" are quite correct, and may be taken as authoritative.—G.

[5641].—**Flues.**—In reply to "B." the size of chimney flue generally adopted is 9in. x 14in. This is according to the Chimney Sweeps Act. This size saves cutting of the bricks, and is eminently adapted as a smoke-producer. The excessive amount of cold air which passes up a chimney of that area will prevent in an admirable manner the consumption of the unburnt carbon, which of course adheres to its sides, and requires the sweeper's constant attention. It is a most antislud size for promoting draughts, &c. Of course the size enables the sweep to use his sweeping appliances most effectually. If I remember right Mr. B. H. Thwaite (*vide* "Hygiene") proposes separate outlets for animal and gaseous products of combustion. If "B." will examine a 5in. diameter American stove-pipe he will find it prevents the formation of smoke, and that 24 square inches area is ample for carrying away products of combustion from an ordinary fire. And no doubt if fireplaces and flues were constructed on scientific principles the sweep's occupation would be gone, as the existence of such a craft is only another instance of an utter disregard for science.—O MORES.

[5641].—**Flues.**—With reference to remarks from "B." about flues, it is obvious that, as the smoke

naturally assumes a cylindrical form in ascending the flue, a circular section is best. This form, for constructive reasons, is chiefly confined to concrete buildings or when pipes are used. In brickwork a square flue is more suitable than one of a rectangular section, as the smoke is less likely to spread and get chilled lagging in the corners. The smaller section of the square flue produces a better draught, and is more easily swept. For ordinary house fires a flue 9in. square is ample, and, as a rule, this is the size adopted in practice. A larger section was necessary when the climbing method of sweeping was in vogue.—C. W.

[5642].—**Defective Drains.**—"A Subscriber" had better report the case he complains of to the local sanitary authority, and if they take no notice the Local Government Board ought to be written to, so that the landlord may be compelled to adopt some remedy. The best mode of preventing the rise of noxious gases would be to excavate a trench along the line of sewer in the basement, and to fill in the same with concrete. Stoneware or iron pipes are better than brick drains in such a position. Another suggestion I would make is that at the highest end of such basement drain, or at any other convenient point, a ventilating pipe should be carried up, either to enter a flue or quite independently on the outside of house. The outside traps should also be ventilated.—G. H. G.

LEGAL INTELLIGENCE.

METROPOLITAN BUILDING ACT, 1855.—District Surveyor for East Hackney (North) v. Sawin Bros. and Co.—Heard at Worship-street Police Court before Mr. Bushby, the 19th December, 1878, and 16th January, 1879.—An outbuilding (400.1) had been erected against the residence No. 102, Clapton-common (1,300.4), but it had no internal communication with the house. The district surveyor followed the decisions in the cases of *Badger v. Corbett* (*Builder*, 19th March, 1859), District Surveyor of St. Margaret v. Biss (November, 1871), and *M. B. W. v. Flight* (*Times*, 19th June, 1872), regarded the outbuilding as an addition to the dwelling and claimed £1 12s. 6d., a half fee upon the area and stories of the house and outbuilding together (1,400.4). The solicitor for the defendants contended that the outbuilding was a separate building, and the fee charged should have been 15s. per cent., as for a new building under 400 square feet in area and the story in height. The magistrate gave a written decision as follows:—"Two questions arise here. 1st. Does the separate entrance make this a distinct new building instead of an 'addition'? 2nd. If not, is the half fee to be reckoned on the single story, and the area of the addition on the stories and area of the original building plus the addition? As to the first question I think that the new building being subordinate to and for the commodity of the original building the separate entrance only makes the former an attached building as distinguished from what with a common entrance would be a mere extension of the original building. The note to the 2nd schedule provides expressly for an attached building by ordering that its area shall be added to that of the main building in estimating the fee for the whole. And this would be for the owner's benefit where instead of being as here a subsequent addition, the attached building was constructed together with the main building—e.g., where the area of the main building was 300 square feet, and that of the attached building 100 square feet, both would be covered by a single minimum fee of 30s. As to the 2nd question I adopt Mr. Arnold's reasoning in the case of the District Surveyor of St. Margaret's, Westminster, v. Biss—viz., that an 'addition' falls within the same rule as an 'alteration.' Now, if instead of an addition say a chimney had been altered, the half fee which is to be reckoned on stories and area could be reckoned only on the stories and area of the main building, including the chimney. That method, therefore, must be followed here, and the defendant is ordered accordingly to pay 32s. 6d. per cent., claimed, and 2s. costs.—Signed, H. J. BUSHBY."

INJURY FROM BUILDING OPERATIONS.—At the Common Pleas Division, Dublin, on January 16th, the action of Graham Lemon v. Meade and another was re-tried before Mr. Justice Harrison. It was to recover damages, laid at £900, for alleged negligence on the part of the defendants' servants, whereby the house, 47, South King-street, Dublin, was injured and fell. The case was tried at the Easter sittings, 1878, before Mr. Justice O'Brien, and after a hearing of six days resulted in a verdict for defendants, but the jury also awarded plaintiff one farthing damages. Defendants were, it seemed, engaged by Messrs. Gunn to build the Gaiety Theatre; operations were commenced in March, 1871, and the theatre was opened in November of the same year. Plaintiff's house, which immediately adjoined the theatre, fell on the 18th April, 1875, having, it was contended, been injured by the building operations. The defence was, that the house fell by reason of old age, having been erected nearly 200 years ago. The case now came before the court on defendants' motion, showing cause against making absolute a conditional order obtained by plaintiff to set aside the verdict on the ground that it was

against the weight of evidence and the reception of illegal evidence. The court allowed the cause shown, and discharged the conditional order, but gave no costs against plaintiff.

THE DRAINAGE OF COLCHESTER.—At Colchester county-court, on Wednesday week, actions were entered by Messrs. Marriage, of East Mill, and Mr. E. Chopping, of Middle Mill, against the Corporation of Colchester for breach of the Public Health Act and the Rivers' Pollution Prevention Act by continuing to allow the sewage of the town to run into the River Colne, by which the plaintiffs alleged that they not only suffered inconvenience, but that the health of themselves and their employes were prejudiced. The cases were exactly similar, and that in which Mr. Chopping was the plaintiff was taken as a representative one. In the opening address of counsel it was shown that correspondence had for the past ten years passed between the Local Government Board and the urban authority, the former body urging the necessity of some other system of sewage disposal than passing it into the river, and the latter promising to take steps, although nothing had been practically accomplished. It was also stated that it would be shown by medical evidence that an outbreak of typhoid fever which occurred at the east end of the town in 1874 was attributable to the discharge of sewage into the Colne, and the judge (Dr. Abdy) was asked to grant an order for the discontinuance of the nuisance. At this stage of the proceedings a conference took place between the town clerk and plaintiffs' counsel, which resulted in a compromise, of which the principal feature was that the Corporation undertake within two years to provide a proper system of drainage by which the outfall into the river will be avoided.

AN OFFENSIVE MANHOLE.—In the Chancery Division of the High Court of Chancery, on Thursday week, the case of *Swanston v. the Twickenham Local Board* was heard. This was a motion on behalf of plaintiff for an injunction to restrain the Local Board of Twickenham from continuing to use a manhole, which was constructed close to a house belonging to plaintiff, and through which manhole access was obtained to the common sewer. There was evidence to show that scarlet fever had existed in the district, and that one case in particular had probably been caused by the effluvia arising from the manhole in question. In support of the motion it was submitted that the only power given to defendants by the Act 38 and 39 Vict., cap. 35, was to work under and through any property, unless they gave the proper notices for purchasing the property, and that otherwise they had no power to open the ground for the purpose of constructing the sewer. The Vice-Chancellor said the question raised in this case could only be determined at the hearing; but, in the meantime, defendants could cover up the manhole in such a manner that no effluvia could arise from it, and further they must undertake not to proceed under their notice as to opening fresh holes without giving plaintiff a week's notice of their intention, in order that plaintiff should have time to take such proceedings in the matter as he should be advised.

A new hotel and restaurant are about to be erected at Fort Opus, Austria, for Mr. Grossi. The building will be 4 stories high, including basement, and will cover about 324 square yards of land. It will stand in an elevated position at the junction of two rivers. The materials used will be red brick, with local lime stone dressings to the doors and windows, and the roof will be covered with red tiles. The architect is Mr. G. H. Thomas, 32, Lord-street, Liverpool.

WATER SUPPLY AND SANITARY MATTERS.

GOOLE, YORKSHIRE.—Mr. E. C. Buchanan Tudor, the town surveyor, has been requested by the Goole Local Board to design sewerage works for old Goole district. The scheme is now completed, and comprises a brick main tank egg-shaped sewer with ventilating man and lamp-holes, penstocks, sluice chambers, stop valves, storm and flow, &c., and the outlet pipe is of cast iron with piled and concrete foundations. The sewerage is to be carried into a tidal estuary, known as the Dutch River, below low water mark.

HOVE.—A Local Government Board inquiry was held at Hove-next-Brighton, on Friday last, before Mr. Arnold Taylor, inspector, with reference to an application from the Town Commissioners of Hove for sanction to borrow the sum of £1,550 for works of sewerage, sea defence, and for providing an infectious diseases hospital. Considerable opposition was raised to the last-named item, and it appeared that the hospital plans were not yet prepared. The remaining items were unopposed, and included £1,500 for a new sewer in Hove-drive, £520 for improved sewer in George-street, and £450 for new groyne to protect the beach from the effects of the private groynes constructed westward of the district. Mr. E. B. Ellice-Clark, the engineer to the board explained the plans, and stated that the works would be carried out by the town commissioners' staff, and that the last works sanctioned by the higher authority were executed in this manner, and at a saving of something like £1,500 or £2,000 upon what they would have cost if done by contract.

A series of water mains are proposed to be laid through the main streets of Harlow and Epping and other villages on the high ridge running through the Forest of Epping for the better supply of the district, which has often suffered from shortness of water. Messrs. Russ and Mians, of Westminster, are the engineers of the scheme.

The Town Council of Nairn have instructed Mr. Willet, C.E., to prepare an amended scheme for the drainage of the town.

The Local Board of New Swindon resolved on Wednesday week to adopt plans prepared by Mr. W. Drew, their surveyor, for alterations to the sewage farm at Rodbourne. The estimated expense is £500.

The School Board for Ashford, East Kent, have accepted the tender of Mr. Fowler for the erection of new schools in the Beaver-fields, Ashford.

The tender of Mr. George Baines has been accepted by the School Board for Millom, North Lancashire, for the execution of alterations and additions to a school at Haverigg.

Mr. M. F. C. Turpin asks us to state that the carved oak chimney-pieces and parquet floors in the new buildings at Chelsea, described by us last week, were manufactured by him.

Works of drainage are about to be carried out at Denbigh. Mr. Clough is the engineer, and the first contract has been given to Mr. Jeffreys.

The Biggleswade Board of Guardians have instructed their architect to prepare plans for a brick small-pox hospital to contain 12 beds, and to cost less than £3,500.

New grammar schools are about to be commenced at Nunaton; Mr. Thomas Smith, of Eaton, is the contractor, for £3,150.

Our Office Table.

THE following private bills have come before the examiners at Westminster this week, and in each case it was decided that the standing orders of the House had been complied with:—The Electric Lighting Bill, which is to empower the Electric Lighting Company to break up, open, or interfere with any streets, public places, &c., in the metropolis, that may be necessary for the purpose of laying down their electric wires; the East and West India Dock Bill, which is to authorize the company to acquire additional land in the neighbourhood of, and for the purpose of extending, the existing docks; and the New River Company Bill, which is to enable the company to raise additional capital. In the case of the Tower High Level Bridge Bill, which came before the examiners on Saturday, and was adjourned, it was decided that the standing orders of the House had not been complied with, and the bill will therefore have to go before the Standing Orders Committee.

THE authorities of the City seem not to know their own minds. Some years ago they decided that Ludgate-hill was to be widened, and a magnificent view of the western front of the metropolitan cathedral was promised. Leases and houses were bought up at a considerable cost, and all the lower part of the hill was considerably widened by the setting back of the new houses. Soon, however, the railway bridge, which now obscures the view, was sanctioned by Parliament, and apparently but faintly opposed by the City. Still buying up and setting back of houses went on spasmodically, and no small amount of money was swallowed up. A rumour, however, has now got about, and events seem to prove its consistency, that the City is tired of its artistic fit, and that the widening of Ludgate-hill, which the necessities of traffic demanded as imperiously as the interests of art, is to be abandoned.

THE late Mr. John Johnson, a notice of whose death appeared in the BUILDING NEWS of the 3rd inst., was not only well known as an architect, but was also celebrated as a piscator. His demise is thus noticed in the *Fishing Gazette*:—"The death is announced of Mr. John Johnson, at his residence, 14, Buckingham-street, Adelphi. In the piscatorial world he has left behind him the name of a famous angler, and the books of the Piscatorial Society, of which he was a very old member, record some wonderful takes of fish in the earlier portion of his life. In the year 1866 he obtained the leading prize for the greatest weight of fish, there being a total of something like 550lb. placed to his credit. He was also, up to the time of his death, the author of the club, in conjunction with his old friend, Mr. Thomas Gillatt. There was a general expression of regret at the meeting on Monday evening last at losing so excellent a member, and the friendship of one whose kind, liberal, and hospitable disposition endeared him so deeply to all. Of late years he

has not very frequently attended the weekly meetings; but on all other occasions he was to be found amongst his old associates. The late Mr. Johnson was also an old member of the Thames Angling Preservation Society, and for the last ten years as one of its general committee. In the architectural world he was well-known as an architect; and the Alexandra Palace at Muswell-hill is an evidence of his ability and skill in the profession he followed."

We have received a reprint of the address and papers read before the British Association at Dublin last year on "Rivers' Conservation." It is unnecessary here to again allude to the conclusions of the speakers. We gave an abstract of Mr. Edward Easton's address as president of Section G, the gist of which was the intelligent supervision and management of watershed areas as the most economical course to adopt. Those who desire to refresh their memory with Mr. Easton's able address cannot do better than obtain the pamphlet we are referring to, in which will be found papers read on "River Control," by J. Clarke Hawkshaw, C.E., and W. Shelford, C.E.; on "The Effect of River Works or Arterial Drainage Works upon River Floods," by James Dillon, C.E.; on "The Hydrogeological Survey of England," by Joseph Lucas; "The Discharge of Sewage into Tidal Rivers," by H. Law, C.E., &c. Many of these subjects have been noticed in our papers.

MR. SAMUEL TRICKETT writes as follows:—"I notice in your issue of the 17th inst., under the head of 'New Buildings in Chelsea,' you draw attention to the red-brick mansions abutting on Cadogan-square, building by Messrs. G. Trollope and Sons, and you state that 'The balcony is arched above with flat arches, supported on red Mansfield stone columns,' and that 'There is a pleasing harmony of contrast between the warm stone and the brick, which avoids the patchy effect a lighter stone would have had.' I fully agree with your writer in everything he says, with one exception—viz., that the stone is *not* red Mansfield but red Corsehill, which I have been introducing into London for some years, and it is the only red stone of fine even texture which retains its colour."

The manager of the Patent Selenitic Cement Company writes us as follows:—"In your article on the New Law Courts in the BUILDING NEWS, of January 17th you say—'We note that all the internal walls are plastered and finished with "Keene's Cement." We beg to say that they are plastered and finished with Selenitic Cement. Although we take it as a compliment to our cement that it should be mistaken for Keene's Cement (though costing far less), we rely upon your justice to make this correction.'"

A new railway, about twenty miles in length, was opened on Monday, from Okehampton to Holsworthy, and will, it is to be hoped, at no distant date be the means of carrying the London and South-Western Railway into Cornwall. The line was constructed by the

Devon and Cornwall Railway from plans of Messrs. Galbraith and Church, and has now been purchased by the South-Western Railway. Mr. Relf was the contractor, and the cost has been about £12,000 per mile. Passengers who are familiar with the present slow service and had accommodation from Plymouth to Penzance, will wish all success to the new venture of the South-Western Railway Company.

MESSRS. CHUBB AND SON, in a reply to the report furnished by Mr. James Hill to Colonel Wrottesley, on the state of the English lock trade, state that it is incorrectly assumed, both by the colonel and by Mr. James Hill, that all English locks are of one class, consisting "of a number of small parts exact counterparts of one another." In a superior quality of lock it is not desired to make a large quantity precisely alike, which any one of their keys will open, but rather to produce the greatest possible variety of combinations with different keys. In order to effect this a certain amount of skilled workmanship has to supplement the products of machinery, and will always continue to do so. Messrs. Chubb and Son assert that they were acquainted with the workmanship and finish of American locks long before contractors were tempted across the water by large discounts, and while readily acknowledging the general utility and neatness of these goods, they maintain that they show no improvements affecting real security superior to those effected in this country.

MR. THOMAS SOPWITH, M.A., F.R.S., F.G.S., who died at Westminster, on Thursday week, was born in 1803 at Newcastle-on-Tyne. He was for nearly 50 years extensively engaged as civil engineer in mining, railway, and other works, both in this country and on the Continent, and was the author of several works on architecture, isometrical drawing, and mining. In 1828 he was appointed commissioner for the Crown under the Dean Forest Mining Act, and in the same year a communication made by him to the British Association led to the establishment of the Mining Record Office. He was a member of many of the leading scientific societies, and one of the early members of the Institution of Civil Engineers.

SATURDAY was the last day on which the claims under the Epping Forest Act were received by the Corporation, who will now go forward with the work of hearing and adjudging. A case of some interest is at present occupying the attention of the arbitrator. It is that of Mr. Peter Mills, and bears reference to what are known as the "fuel assignments," under which a certain number of persons held permission to cut timber in the forest. The Corporation held that the right included only so much wood as could be used for personal fuel, and being unable to come to a settlement with Mr. Mills, referred it to the arbitrator. As there are several claims of a similar nature this is regarded as a test case, and the decision given will doubtless govern the arrangement of all "fuel assignments." It may be mentioned

that the reeves have been appointed for marking the commoners' cattle in all parishes except that of West Ham. A new road, according to the *City Press*, is being made from Chingford Station to Queen Elizabeth's Lodge. Labourers are already at work clearing out the ponds and levelling the ground. Queen Elizabeth's Lodge has now been formally handed over to the new conservators by the Government.

AN important manifesto bearing upon the present position of the slate trade—the staple industry of North Wales—was circulated by the executive council of the North Wales Quarrymen's Union on Monday. The trade, it is stated, has within the last six months got into one of the strangest and most sudden panics ever known, the present danger being lest the employers should endeavour to push matters too far, and take advantage of the stagnation to repeat their attack upon the union. The council complain of the apparent reluctance of quarry proprietors to continue the practice of making stock preparatory to a revival of trade, the men preferring to work such stock at a most reasonable price rather than having their hours shortened. Looking at the present state of affairs, and that the reason assigned for the reduction of wages and the shortening of hours is the inability of quarry owners to sell the quantity of slates made, the union has resolved upon voting to each member emigrating to America £3 for the first year of membership, and £1 for each succeeding year he has been associated with the organisation; double the amount to Australian and New Zealand emigrants, with a further premium of £2 to all emigrating west of Chicago or to South America. It is anticipated that many unionists will accept these offers, as there is no present prospect of any improvement in the trade, most of the smaller quarries remaining closed, while the larger ones are working only half time.

THE papier mâché enrichments, such as soffit and bed moulds, &c., manufactured by the Papier Mâché Company, are well known. But for the purposes of ordinary cornices in houses of moderate value they have been deemed by the majority of builders to be too expensive for general use, the consequence being that rough and inferior, but cheap, plaster casts have been used. The desire to reduce the cost of papier mâché enrichments, and to supply ornaments in every way superior to plaster, but at less cost than it, has induced the company for the past few months to conduct a series of experiments having this end in view. Having perfected the process, they now offer the large majority of their unperforated patterns of enrichments at half the previous prices. These enrichments are very light, sharp, and clean, extremely tough, being stronger and harder than wood or the ordinary papier mâché, easily and rapidly fixed with common brads to plaster, cement, or wood; they are indestructible and uninflamable; they will not, without deliberate violence, chip or fracture; they will not warp, shrink, rot, or decay; they weigh very little, pack very closely, and cost but a trifle for transport or shipment.

THE BUILDING NEWS.

LONDON, FRIDAY, JANUARY 31, 1878.

THE ST. GOTHARD TUNNELS.

WE have already more than once described the progress and completion of the Mont Cenis tunnel, now a regular highway of traffic, hollowed between the Fourneaux and the Bordonnechian slopes from France into Savoy, of the Graian Alps. Those mighty works were long interrupted by many other causes than the physical difficulties, though these were many, and often surprising, encountered by the engineers. Yet, after the immense task had been accomplished, it was still felt that another had to be attempted, and, if possible, carried through. This was the piercing of the Alps, in the group of them geographically called the Lepontine, whose peaks are all above the snow line, and whose height varies from 7,000 to 11,000ft. above the level of the sea. Within a small distance from the celebrated hospital for the recovery of storm-overtaken travellers rise the sources of the Rhine, Rhone, Reuss, and Ticino. The way over the mountain—historians and gazetteers assure us—has been made the scene of many battles between French and Russians, and what not; but the work now approaching its result is plainly a tunnel, or series and system of tunnels right through and beneath, with a simple view to intercommunication from one to another of the populations divided by these granitic Graian Alps. The enterprise, it must be confessed, has been a long time afoot, but its promoters plead, reasonably enough, that instead of a single and simple hollow through the base of a mountain, beneath which they could make “both ends meet” with a mathematical exactitude astonishing even to the mathematicians themselves, they had to elaborate a labyrinth of passages, through hard rocks, shifting soils, bursting walls, and flowing waters, baffling and perplexing in every direction. They have now, indeed, after years of labour, brought their undertaking to not far from a practical finish—that is, they have excavated in round figures—wanting, however, only inches to be accurate—about twelve out of fifteen thousand yards through the hardest rock on the Switzerland barrier, and they have thus somewhere near three thousand yards of boring to accomplish. Not even so much as this might have been left undone had not the inevitable obstacle of finance arisen in the way. The Germans and the Italians profess themselves to be equally interested in the triumphs or successes of the engineers engaged; but upon the Swiss has been thrown, in a great degree, the practical part of the burden—though with these matters, it will probably be felt, the world outside that of the practical speculators can have very little to do. The grand points are—the objects and progress of these vast works—interesting to all Europe—and the prospects of their completion within a reasonable period. Besides the great leading tunnel, as we have suggested, there are many others—twelve, indeed—the shortest of which (Waren) is 1,106 yards long, while the longest (that of the Olberg) reaches to nearly double that distance. The total length of these subsidiary excavations falls not far short of ten miles. Then there are five minor tunnels—branches, as it were—of from 220 to 550 yards, and 25 between 110 and 220 yards, making in all 52 subsidiary tunnels, containing an aggregate line 16 miles in length. But the utmost height of the mountain is no measure of the depth beneath which the line of the tunnel is buried. The report says:—

“Between Immensee and Goscheneu there will be 33 tunnels; between Airolo and Gribasco, 17. The highest part of the line above sea-level is the big tunnel—3,307ft.; the lowest a point between Cadenazzo and Magadino—675ft. The line will be carried over 64 bridges and viaducts, the longest of which (that of Cadenazzo, in Tessin) will consist of five arches, each having a span of 55 yards. The total length of the Gothard line will be a hundred and fifty-five miles—17 per cent. of it being tunnels, and 1 per cent. bridges and viaducts. In the first instance, the line, for the greater part of its length, will be single; but the tunnels and permanent way are to be so arranged that additional rails can be laid down as soon as the financial success of the enterprise seems to be assured. If all goes prosperously, the entire sweep of iron road, beneath those mountainous masses, will be in available order within the next four or five years at the utmost. The contract for the stretch between Brünnen and Flüelen has just been assigned to a French firm, and few reasons appear why the enterprise should not henceforth progress triumphantly towards its accomplishment.” Thus far the official report, with the semi-official comments upon it.

The professional accounts we receive represent the work of piercing the mass of the St. Gothard Alp as differing, in some material respects from that of executing the Mont Cenis tunnel. The mountain to be penetrated presented greater difficulties; the course to be followed by the excavators was not so clear. The same natural resources, favourable at once to water and to blasting power, were not equally at hand. Nor could the different levels—strange though this may seem in a geometrical age—be taken with similar facility. So, at any rate, it is asserted in the somewhat apologetic report of progress before us. The directors declare that they undertook that which, at the beginning, was affirmed to be a chimerical task—that they have done, in less than a decade, that which Conté, the Italian engineer-in-chief, gave them half a century to do in—and that the penetration of St. Gothard by no means resembles or represents the labour of those who met—not beneath the base of Mont Cenis, it is true, but under that of a neighbouring mountain, where their hammers were heard clinking together, and their voices calling one to another before the last wall of division was broken through. Both the vertical and the horizontal measurements to be taken varied. The gradients were not, by any means, the same, nor was the amount of water to be encountered, or the probable flow of it, judging from speculative surveys on either side. All this made up a complication of obstacles which, within a year or two, may be hoped to have been happily encountered. For, it must not be supposed that, so soon as daylight breaks between one abyss in the St. Gothard mountain and another, therefore railway communication is at once to be established. The perforation, so far, will be merely a long, rough, narrow, shallow, zig-zag hole, opening at both ends, but needing to be rounded into an arch, planned along its surface, enlarged to proper dimensions, and strengthened to suit its ultimate purpose. Even during the preliminary processes, indeed, we find that very varying methods have been employed. There has been less of water pressures applied to the advancing shields, fitted into the cavity as it lengthened onwards from two opposite “attacking points,” in front of the gangs of excavators, and much more of gunpowder blasting, effected by drills through the rock, and the carrying off of débris along a line of rails following the workmen, moment by moment, over every yard of their progress. The cost of the undertaking, no matter

what measurement is taken, has been perhaps greater than that of what was believed to be the crucial burrowing beneath Mont Cenis; but, on the other hand, it is believed that the carrying on of similar operations will be considerably cheapened for the future. And there is a considerable advantage derived from the fact that a definite selection has at length been made from among the many routes preferred, at one time or another, by French, Swiss, Italian, and German engineers. There was one, favoured by the late Count Cavour, through the Valley of the Are, to Modena; another by that of the Dora to Susa, bearing with it, singularly enough, the idea of an American tramway down the slopes of the Swiss mountain. But they all gave way, first to the Mont Cenis, and, second, to the St. Gothard project, of which the one is a fact accomplished, while the other awaits only a fresh accession of effort to push it through. For geologists the later details from St. Gothard must possess a supreme interest, though it may be only permitted here to state that, as in the Mont Cenis excavation, the expectations of hidden waterfalls, dark caverns, masses of shifting sand, deep crevices, and so forth, have, happily, not been fulfilled. It was even supposed that huge iron and copper mines might present themselves by the way, tempting the labourers from their duty, and inducing them to dig downwards, rather than onwards, for their wages. No such discoveries have been made; no such alarms have been justified. It is true that the perforation of the mountain has, at times, gone on with disappointing slowness, though this has been due less to want of energy than to want of money to sustain it; and it is true also that, as in the Mont Cenis enterprise, the St. Gothard excavators have had perpetually before them the dim fear of some buried mountain lake, which might at any moment burst over their heads, but which, hitherto, has not done so, together with that of certain “boiling sands,” supposed to lurk in the same recesses; yet neither these nor the predicted waterfalls or swamps have prevented the steady movement of the rock-piercing machine, whether propelled by water, as beneath Mont Cenis, or in a great measure by steam, beneath St. Gothard. In the latter, however, a particular difficulty has had to be overcome, in even a greater degree than in the former. In both the heat and smoke generated by steam-engines are found to be almost insupportable, and the application of air power, suggested by the Genevese physician, Colladon, and brought into practice by the Savoyard, Sommeiller, in order, as he expresses it, to “tear out the entrails of the Alps,” has not yet gone sufficiently far to warrant any other than, so to speak, empirical expectation from it. In fact, to judge from the official report, it has broken more machinery in the St. Gothard tunnel than it has been able as yet to set in useful motion. To meet this problem, writes the practical author of “Il Trafforo delle Alpi,” it is essential to combine two powers—that of perforation with that of pressure—from both of which he excludes the action of steam, and in both of which he admits the action of pure hydraulics, though the engineers of St. Gothard have in so many ways repudiated them as applied to the dynamics of Mont Cenis. The point is very emphatically stated in the “Rapporto della Commissione Governativa,” just issued, which scouts the idea that the Mont Cenis and the St. Gothard tunnels belong to one and the same class in all particular essentials—that is to say, of engineering works. According to this statement, another substance, another temperature, have to be encountered, and most certainly, under the conditions, another machinery has to be employed. In the St. Gothard Tunnel, for

instance, the exact methods found efficacious in that of Mont Cenis, while it was in course of execution, for keeping out mischievous blasts of the atmosphere, or floods of water, failed entirely, while the work of upholding the tunnelled arch as it made its slow way through the masses of rock and of friable substance, has been altogether different. Where, for example, brickwork was necessary in the former case, to prevent fragments from the friable roof falling, to the inconvenience of the work, a simple indiarubber shield has been found sufficient in the latter. Still, neither has been found adequate to keep out the incessant drip which, the report alleges, keeps the work back an inch where it should be going forward two. It is the result of this which has to be watched for, has to be carried off, must be foreseen and provided against by a hundred mechanical contrivances, a failure in any one of which might delay operations for a month. Thus, an advance-guard of explorers endeavouring, only a few days ago, to secure an arch of masonry, lining a cutting through the natural rock, failed to perceive a stream of damp pouring through a fissure, and the entire mass of masonry came down at their feet almost before they had time to escape from it. They still complain, however, in the St. Gothard that they are exposed to gunpowder fumes, suffocating in the narrowness and dampness of that excavation, and that their task is thus rendered both dangerous and slow, as all such labour, indeed, must necessarily be. But it is necessary, at all times, to bear in mind the circumstance already pointed out, and which is insisted upon, with equal emphasis, by the French and the Italian engineers—that these two vast enterprises, though both of them were designed to construct practicable roads through the Alps, instead of over them, are not, in the strict sense of the term, parallel undertakings. They differ from, in point of fact, in almost as many respects as they resemble, each other, though, undoubtedly, they have a common object with a result in view which science, mechanics, and civilisation would alike welcome as a triumph.

THE BUILDING ACTS' AMENDMENT ACT.

AFTER a considerable lapse of time the Metropolitan Board of Works have given notice of their intention to apply to the Secretary of State for the Home Department for a confirmation of the new bye-laws. These have been published, and we may now take a general view of the amendments proposed, as they will affect buildings within the jurisdiction of the board. First, as to foundations and sites, it is enacted that "no house, building, or other erection shall be erected upon any site or portion of any site which shall have been filled up or covered with any material impregnated or mixed with any faecal, animal, or vegetable matter, or which shall have been filled up, or covered with dust or slop, or other refuse," or upon which any such matter has been deposited, unless such matter or refuse shall have been removed, any excavation being filled up with hard brick, rubbish, or similar material. The above provision will effect certainly a vital reform in the sanitary welfare of the metropolis; but so far as we can see, there is one case the wording of the clause will not touch—namely, a site already impregnated with old cesspool or leaky drain matter. The clause simply prohibits building on a site which has been "filled up" or "covered," and does not apply to sites in which the mischief exists in the native soil. If, instead of the words introduced, the clause ran, "any site in which old drains existed," &c., every conceivable

form of danger arising from the soil would have been met. But we find a layer of concrete, 6in. thick, smoothed on the upper surface, is to cover the site; and this will mitigate, if not quite exclude, any dangerous emanations. With regard to footings, we find in future every builder must lay his footings on a "bed of good concrete, at least 12in. thick, and projecting 6in. on each side of the lowest course;" but it is not very clear whether all walls are intended: we take it to be so. Is this necessary in all cases in addition to the layer previously mentioned? How many builders, we wonder, will not think this a useless restriction? That the concrete be real—not a mixture of rubbish—another clause provides that the material (gravel or hard brick) be approved by the district surveyor, and that the proportion of lime or cement be 1 to 6, or one of cement to 7 of other material. Even this clause the cunning builder might evade, however; for it only says the gravel, or hard material, is to be approved, the lime being exempted from inquiry, as also the mode of mixing.

On the substance of walls we find some bye-laws that will make good many of the flagrant omissions of the present Building Act. Thus we find in brief the walls of every building shall be constructed of "good, square, hard, sound, and well-burnt bricks or stone" properly bonded; that good mortar, composed of good lime and clean sharp sand, properly washed, or grit in the proportion of 1 of lime to 3 of sand or grit, shall be used; that cement should be Portland or other cement of equal quality, "weighing not less than 112lb. to the struck bushel and capable of maintaining a breaking weight of 350lb. per square inch, after being made in a mould and immersed in water for seven days;" that stone used must weigh not less than 110lb. per cubic foot, be free from vents, &c., and laid on its natural bed; that a damp-proof course of asphalt be laid throughout the thickness of every wall "at a height of one foot above the base of such wall where there is no basement, and at a height of one foot above level of ground where there is a basement or half basement story;" and lastly that the top of every party wall and parapet wall shall be finished with a course of hard well-burnt bricks set on edge in cement, or by a coping waterproof and fire-resisting. It appears hardly credible that such necessary clauses should have been ever wanting in the former Act, for they are simply what every architect's specification requires; and we may well shudder to think how many rotten, ill-bonded, and dangerous walls have been suffered to be built during the last 50 years.

The next sections, 3 and 4, relate to the duties and fees of district surveyors, but we would incidentally remark that the present organisation is manifestly unable to cope with the duties of inspection. We have only to walk round some of the metropolitan districts to see that buildings are erected and occupied without even a visit from the surveyor or his deputy, and we point to the almost universally admitted necessity that qualified inspectors should be appointed in every district, to act under the surveyor, for we know that many faulty buildings and dangerous structures come to the knowledge of the surveyor indirectly, and not from examination. Sections 3 and 4 are as follows:—

It shall be the duty of each district surveyor, on receiving notice of any house, building, or other erection, or alteration, or addition, or on his becoming aware that any house, building, or other erection or alteration, or addition, is being proceeded with, but in respect of which no notice has been given, to see that the provisions of the foregoing bye-laws are duly observed, and to see that the terms and conditions of any permission are complied with (except in cases where the board may have dispensed with the observance thereof).

As to the fees to be paid to district surveyors,

in every case in which proceedings may have been taken by the district surveyor to prevent the erection of any house, building, or other erection upon any site, not in accordance with the provisions of the bye-laws, in relation to sites, and in which the site may have been subsequently made conformable to the provisions of such bye-laws, there shall be paid to such district surveyor a fee of 10s. for each house, building, or other erection, erected on such site, in addition to any fee to which he may have become entitled under the provisions of the Metropolitan Building Act, 1855.

Section 5 relates to the deposit of plans and sections, from which it appears that on notice being given to the district surveyor of the erection or alteration of any public building, plans and sections of such building be deposited with the surveyor for his inspection, that 7 clear days must elapse before any work is proceeded with; and in respect of houses or alterations of buildings other than public buildings, the district surveyor has power to require the production of a plan or plans and sections for his inspection, and no work is to be proceeded with until such production of plans has been complied with. Section 6, as to the deposit of plans and sections of buildings to which section 56 of the Metropolitan Building Act applies, makes it compulsory for every person, who wishes to erect a furnace, chimney-shaft, or to build in concrete, to deposit plans and sections of the same with the surveyor, to be retained by him, and if the surveyor is satisfied that such building is to be constructed in conformity with certain rules he may permit its erection, but the Board reserves power, where the surveyor has declined to grant permission, to permit its erection. We here give the gist of the rules in each case. As regards furnace chimney-shafts of every kind, brick and mortar, or cement of the best quality, is required; the foundations to rest on a bed of concrete; the shaft at the base, if square, is to be at least one-tenth of the total height of shaft; if octagonal, the external width to be one-eleventh of height; and, if circular, one-twelfth of the height. A batter is to be given to the shaft of 2½in., at least, in every 10ft. in height; the brickwork to be at least 8½in. thick at top for 20ft. below, to be increased 4½in. in thickness for every 20ft. of additional height, measured downwards; the footings to spread equally all round by regular offsets to a projection equal to the thickness of the enclosing brickwork at base, and no portion of the enclosures of a shaft shall be constructed of fire-brick, any lining of that material being in addition to the thickness and independent of brickwork. No cornice is to project more than the thickness of the brickwork at the top of shaft, and it is further ruled that no iron cap shall be less than 1in. in thickness, and must be held down by iron bolts.

The rules relating to concrete buildings are important. The ingredients to be composed of Portland cement, with clean Thames ballast, clinkers, or any hard material, each to be passed through a mesh not exceeding 2in. diameter. Sand must be added to such materials in the proportion of 1 to 2; the mixture must be in the proportion of not more than 6 parts of material to 1 part by measure of Portland cement. In making the concrete, a box of 2ft. x 4ft. x 2ft. is to be used for the materials, and another holding one sack or half a cask containing two bushels of the cement, the ingredients being turned over at least three times, and thoroughly mixed together with water. The walls to be carried up in regular layers, grouted in cement and sand of 1 to 2, the grout to be made as mortar, and then thinned. The thicknesses of walls are to be equal at least to those for brickwork prescribed; cores to be provided for flues and recesses; and doors and window frames to be built into the walls. Above the roof the stacks and party-walls

to be rendered in cement. In respect of fees it is provided a fee of one-half more be paid to surveyor than the fee he is entitled to for new buildings or additions. There is little in these regulations that can be objected to, though they rather interfere with any special system of concrete building.

Clause 7 empowers the board to remove any house or building not constructed in accordance with these bye-laws or other terms and conditions, after notice shall have been given either by the board or district surveyor to alter or pull down to the occupier, owner, or builder, and the same remains uncompleted within 28 days after service of notice. Penalties for breach of any of the bye-laws not exceeding 60s., nor less than 20s. for each offence are to be enforced, and in case of a continuing offence a further penalty, not exceeding 30s. nor less than 20s., for every day after notice from board or surveyor. The board, however, reserve to themselves the power to dispense with the observance of any or either of the bye-laws under conditions they may think proper. This discretionary power is very necessary if acted upon with impartiality and justice, and will tend to allay any feeling of opposition to bye-laws that will appear to many as a further encroachment upon private interests or restriction of enterprise by the board. We may just remark, however, that the intention of the original framers of Metropolitan Building Acts was evidently to guard against the erection of buildings of a combustible nature, and not to frame a code of building regulations perfect in all respects. This is evident from the fact that the first legislation in this direction, in the reign of Charles II., had reference to a prevention of fire, and arose after the Great Fire of London. In Queen Anne's reign other Acts were passed, the chief object of which was to prevent fire, and to regulate the construction of party walls, and during the Georges' era several repeals of former statutes took place—all of which, by their titles, show clearly that the principal aim was the regulation of party walls, flues, and other structures, with the intention of reducing the risks of fire. The old Act of George III., indeed, incorporated the provisions of former statutes, but was always a stumbling block to lawyers and builders. It was a clumsy patchwork at the best, and acute builders were not slow in evading its provisions. It is high time, therefore, that rules of a more general nature should be introduced, and till we have a more scientifically-constructed code, we must take the proposed bye-laws as the only alternative rendered necessary by the increasing exigencies of building in the metropolis.

ARCHITECTURAL GEOLOGY.—II.

SECONDARY FORMATIONS.

UNDER this title English geologists have included all those strata of the earth's crust which lie between the newest member of the cretaceous or chalk formation and the oldest of the new red sandstone series. They are composed for the most part of solid rocks, possessing more or less hardness—many of them yielding excellent building stones, while others are valuable only for burning into lime. Beds of clay and sand also occasionally occur.

Chalk.—In this country the cretaceous series is the one which in point of antiquity appears to immediately have preceded the "London clay," since one or other of its members is always found below that deposit, having been reached at a depth of 160 feet by boring in the centre of London, and within 70 feet at Harwich. But although this series is always to be met with below the London clay, yet the latter is not always found overlying it, as the chalk

comes to the surface over a large portion of the eastern and southern counties, but in some cases is covered up by a deposit of "drift" or "alluvium," as alluded to in our previous article. In fact, this formation is one of the most extensive in the world, and appears to have been originally deposited in a deep and open sea, consisting, as it does, mainly of minute shells and other organic remains. In England we find it near the surface as far north as Flamborough Head, in Yorkshire; and on the south coast, stretching from Margate on the east to the borders of Devon on the west; it covers a large portion of the East Riding of Yorkshire, forms the wolds of Lincolnshire and the greater part of Norfolk, with parts of Suffolk, Cambridge, and Hertford. It also is seen in the counties of Buckingham, Oxford, and Berks, and over a large portion of Wilts, Dorset, and Hampshire. In Sussex we find it extending along the coast, in a series of undulations, from Beachey Head to Littlehampton; in Kent it may be seen all over the north and east districts; and it forms a great portion of the range of the Surrey hills, around Caterham, Epsom, Rugall, Dorking, and Guildford. In many of these districts the chalk is obtained close to the surface, but in others it is necessary to dig down to it through the more recent deposits of gravel, sand, or clay. The upper, or white chalk, is a soft limestone, of which 98 per cent. is pure carbonate of lime, with nodules and bands of flints, consisting of nearly pure silica, but quite free from layers of sand or pebbles. In Buckingham and the neighbouring counties the upper chalk, with flints, attains a thickness of 300ft., below which is a thin layer of hard chalk rock, and then from 400ft. to 500ft. of chalk without flints. In the counties of Oxford and Berks the chalk rock is from 6ft. to 12ft., while in Wilts, and at Weymouth, in Dorset, it is 800ft. thick. In Surrey its thickness varies from 350ft. to 500ft., and in the eastern parts of Kent and Essex it reaches 800ft. Under London the average thickness of chalk is 640ft. The upper chalk is not generally fit for use as a building stone, but is extensively employed for making lime—producing a rich or fat lime, which will only set firmly in dry air when used as a mortar. The soft chalk is also in many places made into "whiting," by grinding it with water to a fine pulp, allowing it to flow into a series of tanks, and then forming the sediment into cakes, and allowing them to dry. The flints, which may be obtained in large quantities from the chalk, are much used in their own localities for walling, and also in the manufacture of porcelain and glass. The places near London where chalk with flints is obtainable are—Lewisham, Charlton, Greenhithe, Gravesend, Bromley, and Chislehurst, in Kent; Purfleet and Grays, in Essex; Sutton and Croydon, in Surrey. Blocks of sandstone of considerable size are sometimes found embedded in the chalk, and are used for building purposes. The chalk obtained at Reading and Kintbury, in Berkshire, and also that from Hesse Cliff, near Hull, is used for making lime and whiting.

The lower, or hard chalk, is often quarried as a building stone in Norfolk, as at Stoke Ferry, Hunstanton, and at Markham, near Swaffham, while that at Cromer and Trunch, near North Walsham, is only used for lime. In Suffolk we find chalk boulders embedded in the gravel and clay which can be employed as building stones after being hardened by exposure to weather and frost. The Totternhoe stone of Bedfordshire is a hard and brownish sandy chalk, which has been much used for building in Dunstable, Luton, and the neighbourhood; but it is only adapted to interior work which is not exposed to the weather. The Beer stone, found near Axminster, is also a hard chalk,

and has been largely used at Exeter and its neighbourhood in building the cathedral and other edifices. In Wilts the chalk is quarried for building stone at Netherhampton and Alton, near Devizes; and in Hampshire there are numerous quarries in different parts—as at Basingstoke, Andover, Kingsclere, Winchfield, Sherborne, and Whitechurch—the softer chalk being used for lime and the harder as a building stone. In Sussex the chalk quarried near Steyning has been employed in building the priory and other edifices at Lewes; and in Surrey that obtained at Shalford, near Guildford, is much used as a building stone in the locality. At Saxby, near Grantham, a hard chalk is also quarried as a building stone.

Upper Greensand.—This name is given to a small set of beds, varying from 20ft. to 80ft. in thickness, which in some places is found at the bottom of the upper chalk, and consists of greenish-grey sand and sandstone. It is chiefly noted for the "firestone" which is obtained in Surrey, about Merstham, Reigate, Betchworth, Godalming, and Godstone, where it is quarried in slabs about 10in. thick—which are used for floors of glass-furnaces, backs of fireplaces and stoves—and is occasionally employed as a building stone in the neighbourhood of the quarries. It is chiefly known in London as "hearthstone," being used for cleaning hearths and other stonework. In Sussex we find these beds yielding a sandstone at Pulborough, with which Arundel Castle and other buildings in the locality have been erected; also a similar stone at Coultershaw, which has been used in Tillington and Petworth churches. A stone of a chalky appearance, called "Malm rock," is also found in Sussex, at Petersfield, Pulborough, and Hassocks-gate, and near Alton, in Surrey, where it is used as ashlar facing and for chimney-pieces. In the Isle of Wight these beds yield a calcareous sandstone, quarried at Shanklin-down and other parts as a building material. In Dorset the beds of greensand are conspicuous—a yellowish-brown sandstone being obtained at Lyme-Regis, and a calcareous sandstone grit near Chard. A siliceous bed of building stone, about 5ft. thick, is found at the base of the chalk near Widworthy; and beds of sandstone, with brown and grey sand below, are quarried in North Wilts, near Devizes and Seend. In Berks this formation consists of soft dark greensands, 20ft. or 30ft. thick, overlying some beds of a whitish siliceo-calcareous stone, which is quarried near Wantage and Wallingford.

Gault is a stiff blue clay—sometimes calcareous and micaceous—chiefly valuable for making into bricks, tiles, drain-pipes, &c.—and is found between the upper and lower greensands. Its greatest thickness is in Oxford and Berks, where it is 250ft.; and in Bucks it is 130ft. thick. At Maidstone its thickness is 150ft., and at Folkestone and in the Isle of Wight it is 100ft. Under the middle of London it has a thickness of 130ft., below the London clay; while at Harwich, under the same formation, it is only 40ft. In Norfolk it is found at Stoke Ferry, and is 24ft. thick at Norwich. In Wilts the gault varies from 80ft. to 140ft., being made into bricks at Devizes, Warminster, Downton, Trowbridge, and Westbury. In Cambridgeshire the clay is 150ft. thick, pits of it being worked for brick-making at Barnwell. In Kent there are extensive works—at Maidstone, Aylesford, and Burham—of brick, tile, drain-pipes, and terra cotta, manufactured from the gault clay. At Shaftesbury, in Dorset, the gault contains a valuable bed of sandstone, which is much prized in the locality for building, on account of its power of resistance to weathering.

The **Lower Greensand** consists chiefly of beds of sand with calcareous sandstones,

some of which are largely used for building purposes, as the "Kentish rag" and the "Bargate stone," the former of which is found in Kent, at Hythe, Folkestone, Godstone, Maidstone, and Boughton, together with a sandy stone known as "Hassock," and used as a backing to walls faced with the "rag." The Kentish rag contains 92½ per cent. of carbonate of lime, and 6½ per cent. of earthy matter, with small quantities of iron oxide and carbonaceous matter; while the Hassock has only 53 per cent. of lime, with 32 of silica, 4 of alumina, and 8 of iron oxide, with phosphates in small quantities. The Bargate stone is a calcareous sandstone or grit, found in Surrey, near Godalming and Dorking, being used for walling in that neighbourhood. In Norfolk some hard beds of stone, suitable for building, are obtained from the greensand, together with beds of red and white sand. Valuable beds of gravel are found in this formation in the vicinity of Woburn, Leighton, Ampthill, Sandy, Wicken, Potton, and Upware. In Wilts it yields calcareous sandstone at Lonsdale; red or yellow ferruginous sand and gravel at Swindon; and at Farringdon, gravel, sand, and hard beds of stone used as millstones.

The *Wealden* formation is so called from being chiefly found in the "Weald" of Sussex, and in adjoining parts of Kent and Surrey, where the chalk which at one time covered it up has been entirely swept away. It is a fresh-water formation, consisting mostly of clay or shale, brown or blue, with occasional beds of sand and sandstone, and a highly fossiliferous limestone, sometimes called "Sussex marble," which has been much used in the older churches of the Weald. The "marble" is found near Beddenden, Staplehurst, Crowhurst, Chiddingfold, Petworth, Betherden, and Clayton. At Horsham is quarried a calcareous sandstone, capable of being split into thin slabs, and much used in the neighbourhood for walling, paving, and roofing; the same kind of stone is also worked near Itchingfield and West Grinstead. The Tilgate stone, obtained near Horsham, is also used for local buildings, and a similar one is quarried near Hastings, and at Wadhurst near Tunbridge Wells. Beds of sandstone, impregnated with bitumen, are found at Chichester, and are said to have been used in building Pevensey Castle. The Calverly sandstone, obtained near Tunbridge Wells, has been largely used for the local buildings; it contains 94 per cent. of silica, with iron, magnesia, and alumina. A sandstone found at Edenbridge is used in local buildings; and at Battle the Sussex limestone is burnt into lime.

The clay of the *Wealden* is used largely in many parts of Sussex and Surrey for the manufacture of bricks, tiles, drain-pipes, and pottery, as at Hastings, East Grinstead, Lewes, Burwash, Petworth, Midhurst, Burgess-hill, Reigate, and Dorking. The Weald clay is also used for similar purposes at Weymouth, in Dorset. The thickness of this formation is very variable, being greatest near Leith-hill, on the south-west of Dorking, where it is 1,000ft. To the north of Flamborough Head, in Yorkshire, there is a bed of clay supposed to belong to this formation, in which are found large quantities of septaria, much used in cement manufacture.

EGYPT UNDER THE PHARAOHS— DERIVED FROM THE MONUMENTS.*

IT is surprising how archaeological research is undermining the reputed authenticity of the old historians, but in no domain of inquiry do we find the conflict

between fabulous narrative and the testimony of the monuments so remarkable as in that of Egyptian antiquity. Young and Champollion were probably the earliest who tore the veil of tradition and obscure written history from the contemporary records of the land of the Pharaohs, but to Dr. Henry Brugsch-Bey we must ascribe the honour of having divested the Egyptian records of the unreliable and coloured accounts that for ages have obscured them. The other day it was our pleasing task to notice briefly Dr. Birch's edition of Sir Gardner Wilkinson's interesting work on "Egyptian Manners and Customs." It is now our duty to introduce to our readers a work on the "History of Egypt under the Pharaohs," based entirely upon the monuments. This task was undertaken by Dr. Henry Brugsch upwards of twenty years ago, and we have now a translation from the German of his great work, completed and brought down to the present day, by the late Henry Danby Seymour and Mr. Philip Smith, B.A., and published by Mr. John Murray. Of course, it would be absurd to attempt in our brief review anything like a complete sketch of Dr. Brugsch's work. The editor premises, "in rendering into English Dr. Brugsch's German translations of the Egyptian texts, that there has been a twofold difficulty, chiefly from the obscurity of the originals, and partly also from the archaic German often used by Dr. Brugsch to imitate their style." He also refers to the author's long and deep study of Egyptian antiquities, his knowledge of the life and character of the people and the Court of the great Pharaohs, which has enabled him to set in the clearest light the hierarchy, the details of administration, the works of artists, and the connection of Egypt with other nations at the principal epochs of her history. Dr. Brugsch's great work, in short, is a history of Egypt under the Pharaohs, derived from the monuments. Its aim is chiefly to interpret the stone records of a remote age by the light of recent investigations. Of course, we must rest the value of the work chiefly on the fidelity of the translations, which the author observes he has taken the greatest pains to insure. Dr. Brugsch rejects as erroneous many opinions hitherto held by Egyptologists—such, for instance, as a Pelasgo-Italian confederacy of nations in the time of Minephthah I. and Ramses III., and the connection of Ilum and the Dardanians with Egypt in the fourteenth century B.C. Another fact he commends to the student is that the "Egyptian monuments of the date 1000 B.C. and onwards bear witness for the first time to a knowledge of the names of Assyrian kings in the Egyptian form of writing, and attest the presence of Assyrian satraps in the Nile Valley." Thus Panrshus (Parashus), Pallash-nisu, Shashanq, Nimrod, &c., appear in close connection with Egyptian history. As to chronology, the author remarks—"The monuments are now beginning to discredit more and more the numbers of Manetho," whose lists have been taken as authoritative. We dip into the introductory chapter, and find the author writing that the "Tables of Kings" of Saqqarah and Abydos furnish undoubted evidence that the "primitive ancestors of the Egyptian dynasties—the Pharaohs of Memphis—must be greeted as real historical personages, and that King Ramses II. (about 1350 B.C.)—the Sesotris of the Greek fabulous history of the Egyptians—was preceded by at least seventy-six legitimate sovereigns." In other words, there were so many generations of men who lived during a space of time which is greater than the years that have elapsed from Ramses II. to the present day. Such a period of time is truly impressive, and gives us an idea of the astounding age of

Egyptian history and the monuments which mark it—the Pyramids of Memphis. Referring to the origin of the Egyptians, about which there has been much controversy, Dr. Brugsch rejects the Ethiopian origin, believes in the Asiatic beginning of the people, and, as he says, comparative philology has strongly supported the idea that the primitive roots and elements of Egyptian grammar point to an intimate connection between the Indo-Germanic and Semitic language and races. The Ethiopian style of art, as shown by its monuments, carries the conviction, moreover, "that we can recognise no special quality beyond the rudest conception and the most imperfect execution of a style of art originally Egyptian." The oldest starting point in the long series of stone buildings on the banks of the Nile is found in the Pyramids at the apex of the Delta, while on proceeding southwards the stamp of antiquity vanishes from the existing monuments. Chapter III. enters into some interesting facts bearing upon prehistoric Egypt. So far, we are told, as the surviving monuments reach back, their beginnings coincide with the first age of the stone period, which the "scientific student has invented to bridge over the historical chasm with a tangible fact." The prehistoric period was filled up with mythical inventions. Three ages were imagined till the time of Mena, one in which a dynasty of gods reigned; then an age of demi-gods; and thirdly the dynasty of the mysterious Manes. Theology, of course, filled these ages with deified beings. We have, for instance, confirmation in the monuments of the dynasty of the gods. Thus the god, Patah, of Memphis, whom inscriptions call the "father of the gods," is the architect in the highest sense of the word—the word Patah signifying "architect, former, constructor." On the temple of Denderah the inscribed words call the god "the chief of the society of gods who created all being." On the walls of the Temple of Isis at Philæ a similar appellation is given, and the monuments—both Egyptian and classical—prove the supreme place of this god at the head of god-kings. Ra, son of Patah, is represented as the Sun, the representative of light and fire in the series of the four elements; Thui (the air) represents the idea of emptiness; Seb (his son) appears in monuments as the personified image of the earth, the third element, and corresponded to Saturn; Osiris (his son) represented water, and was the symbol of existence completed, the past; Set, the son of Seb, typified the annihilation of being; and lastly Hor (Horus, Apollo) the son of Osiris and of his wife Isis, symbolised the return of completed existence, the new life, the morrow or the future. These names of royal or king-gods are of constant recurrence in the records of Egypt of every period. Of the two fabulous dynasties which succeeded, the monuments preserve little, and the author regrets that the fragments of the Turin papyrus, once containing the most complete list of the kings of Egypt, have not preserved the slightest intelligible information respecting the fabulous successors of the king-gods.

We commend to the perusal of all students the author's interesting remarks on the chronology of the Pharaohs, Chap. IV., in which it will be seen how wide the computations of scholars have been in fixing the date of accession of the first Pharaoh, Mena. The difference between the extreme dates is no less 2,079 years. Thus Boeckh puts it at 5702 B.C., and Bunsen at 3623 B.C. According to Brugsch the account given by the Egyptian priest, Manetho (now lost), was largely corrupted by the ecclesiastical writers who, in error or designedly, falsified the names or numbers. We may simply add that the author has given a chrono-

* A History of Egypt under the Pharaohs, derived entirely from the Monuments. By HENRY BRUGSCH-BEY. Edited by PHILIP SMITH, B.A. 2 volumes. London: John Murray.

logical table, partly compiled from the table of Abydos, based upon the assumption that it is only from the beginning of the 26th dynasty that the data can be considered correct, and assigns the year 4400 B.C. as approximately true.

It is worthy of note that the temple, among the Egyptians as among other ancient nations, formed the centre of every new town, which was built round it. When a new temple was erected a town was soon formed. Thus Memphis, the great capital of the ancient empire, was founded by Mena. The river Nile was diverted for the purpose, its ancient bed filled up, and an enormous dyke was constructed by which the river was carried more to the east of the Libyan chain, and to this day the waters of inundation are restrained from overflowing by its means. "The office of architect," we read, "was the occupation of the noblest men at the king's court. Pharaoh's architects (the *Mur-ket*), who were often of the number of the king's sons and grandsons, were held in high honour, and the favour of their lord gave them his own daughters out of the women's house as wives." We cannot afford space to quote the list of the Pharaohs' architects which time has spared, but they show the importance attaching to the office at that remote period. The successors of Mena are detailed, and there is much to interest the student in the succeeding chapters. Thus the Pyramids of Gizeh are made the subject of some very graphical remarks; their dimensions, as given on the authority of Col. Vyse, show them to differ in breadth and height, and the author solves the enigma of their erection in the only reasonable way—namely, that the pyramid was the outer shell of an inner kernel or sepulchral chamber for the reception of the king's sarcophagus, and that the external structure was added, stone by stone, in a series of steps, while the Pharaoh still lived till it was so huge that no further extension could be made, when a casing of hard polished stone fitted into the steps covered the vast mass. Thus these gigantic monuments grew in size with the king's enjoyment of the sun-god Ra, or during life, commenced as soon as he began to reign, and continued with a firm faith in the eternal resting-place of the body. Each pyramid had its special name. There were the erections of Khufu, of Khafra, and of Menkara. The discoveries of M. De Rougé form an interesting feature in these chapters, and the reader will find the monumental history of the Pharaohs of the 12th dynasty replete with important evidence of the great age of the Usurtasens. The buildings at Heliopolis or On, the monuments at Karnak, the tombs at Beni Hassan, the site of Lake Mæris, are made to illustrate the life and character of this important period of Egyptian empire. Architecture, as M. De Rougé says, shows "inconceivable perfection in the cutting and placing of blocks of great dimensions. The passages of the Great Pyramid remain a model of exactness of building which has never been surpassed." The bas-reliefs of the tombs give us the only idea of the exterior style of the temples of this first epoch. One sole motive of ornament is combined with the severe outline—namely, two lotus leaves placed opposite to each other. The figures and statues have a broad proportion which gradually becomes thinner; the colouring is delicate, and the limestone statues often entirely painted, while those of granite only partially—as the eyes, hair, and drapery. Dr. Brugsch objects to the deprecatory tone of most art histories in speaking of this time, and he says it arises from the complete ignorance of the critics, and from a superficial way of looking at the art. "Egyptian art is art in the noblest meaning

of the word," but it is fetter-bound by traditional usage and rules. The author fully agrees with the criticism of Lepsius in his work "On Some Egyptian Art Forms and their Development," and his answer to the deprecatory judges. Dr. Brugsch also enlightens the art critic who has regarded Egyptian art as mechanical in style, and who believes Egyptian masters never existed. He imputes this idea to ignorance of Egyptian inscriptions, and reminds us that the artist was the most honoured man in the empire, and stood close to the Pharaoh. An illustration of this is found in the inscription on a tomb of an old artist named Martisen, who lived 44 centuries before our time. He calls himself "a master among those who understood art and a plastic artist who was a wise artist in his art," and relates his acquirements. His son, Usurtasen, of whom a pedigree is given, shows that father and son occupied an important position in the arts of the 12th dynasty, and, it is thought, opened the age of highest art development in the old empire.

We pass over several chapters on the irruption of the Hyksos or "Shepherd Kings," at the end of the 13th dynasty, the period of foreign dominion of the Hyksos, and time of Joseph's sojourn in Egypt, during which the monumental records are comparatively silent or obscure. In the 18th dynasty, dated 1700 B.C., we have the building of the great temple at Thebes; records of the Thutmes, Queen Hashop, and her distinguished architect, Semnut, whose buildings are described as the most brilliant and tasteful which were ever erected by Egyptian artists. Thutmes III. reigned 53 years, and was the Alexander of Egyptian history, and from the inscriptions and representations on the temples and obelisks Dr. Brugsch gives us a very lucid picture of the exploits and victories of this mighty monarch. Many of these inscriptions are in a high-flown style. The magnificent temple of Amon at Ape, and the stupendous Hall of Pillars (Khu-mennu or "splendid memorial"), were built by this king, who certainly added more than all other royal builders to the great temple at Karnak. It was during this period, the 16th century before our era, that architecture reached a climax, and excelled in the qualities of mass and sublimity beyond any that followed it. From the southern boundary of Africa to the Mediterranean coast, the ruins of this great dominion still attest its power, and the author describes many of the most important of the temples, and some of the leading architects whose names are inscribed. We may mention Mer, Rois, Amenemant, Amenhotep. We can but glance at the second volume. The reign of Mineptah I. (Sethos) 1366 B.C., was another brilliant one. The monuments once more reflect the victories of the empire, and the temple at Thebes is the prominent landmark. The "Great Hall" at Karnak, with its 134 columns of immense size, still astonishes the traveller; the temple of Osiris at Abydos, and the tomb of Seti, are master works of building, sculpture, and pictorial inscriptions; and the celebrated Table of Abydos, with its list of 76 kings, is important historically. During the reigns of Ramses II. and Mineptah II., the monuments are inferior as works of art, though in Nubia Ramses built many towns and temples, while the rock-cut temple of Ibsambul has remained the wonder of ages. To Ramses III., the "Prince of Heliopolis," may be ascribed the temple of Amon at Medinet Abu, a new Ramessesum dedicated to Amon, but we refer the reader to the author's work. The great Harris papyrus—a new edition of which Dr. Birch has recently given to the British Museum—will always form the most important contribution towards the reign of the third Ramses. In his successors' time architec-

ture fell into insignificance; we can only mention the names of Ramses IX. and the chief priest and architect, Amenhotep, recall the gradual waning of Egyptian power during the 21st dynasty, the foreign irruptions and fall of the Egyptian monarchy in the 26th dynasty, till the period when the history of Egypt gradually merged into that of Greece, or about the sixth century B.C. Art then assumed a greater elegance—a neatness and fineness in execution; the capital of Alexandria succeeded to Thebes, Memphis, and Sais—Persian arms and prowess to the rule of the Pharaohs: and from this point we must continue the narrative with the conquests of Alexander the Great. We will only add the book Mr. Philip Smith has edited for us will be read with great interest by all Egyptian scholars and antiquaries, throwing, as it does, fresh light on many an obscure page of Egyptian history. The volumes are illustrated by coloured plates—one a representation of a tribute from a tomb at Thebes—a portrait head of a wooden statue of an Egyptian ascribed to the 4th dynasty, found at Saqqarah, maps of Upper Egypt, and various valuable genealogical tables, lists of kings, &c.

ARCHITECTURAL ASSOCIATION.

WE publish this week the second portion of Mr. Blashill's paper on "Party Walls: the Law and the Practice," read at the last meeting of the Architectural Association, and the subsequent discussion, in continuation of our report in last issue, pp. 86-8: As to the whole of the rights that are given to the building owner, the author explained the Metropolitan Building Act provides that he shall not exercise them in such manner or at such time as to cause unnecessary inconvenience to the adjoining owner, and we have already seen that the surveyors are to determine the time and manner. The rights of the adjoining owner, as affecting the party structure, are as follow: He may require the erection thereon of certain chimney-jambes, breasts, or flues, or certain piers or recesses, or any other like works for his own convenience, and the building owner must do this if it will not be injurious to him, or cause unnecessary inconvenience or delay. The adjoining owner may require these works to be done by giving a notice, a printed form for which is provided, within one month after his receipt of the party-wall notice from the building owner, or he may do the works himself. If he give a notice, it must be done in the same way as laid down for the notice by the building owner, and if a difference arises thereon it must be dealt with by the surveyors. Sections 89, 90, and 93 give the mode of arranging the payments by the adjoining owner for works done on his requisition. He may demand from the building owner security for costs and compensation before the work is commenced, and the amount of the security is to be fixed by the judge of the county court in case of difference. By Section 92, the building owner is to stand possessed of the sole property in party structure until any contribution which may be due from the adjoining owner in respect of it is paid. This may seriously hamper the adjoining owner in dealing with his property, and may induce him to pay. The party wall, considered as a "dangerous structure," very frequently comes under the notice of the district surveyor. Its connection with the external walls is, indeed, peculiarly liable to cause danger to a building. A case is now under my notice where the front walls of a whole terrace of three-story houses, some fifty years old, have to be taken down and rebuilt, mainly owing to the party walls having been first erected and the front walls afterwards built up against them, without any bond whatever. I know of a case in which this process was reversed. A long façade was first erected, and afterwards the party walls were built against it at such distances as suited the wishes of the purchasers, good bond being of course impossible. New fronts have constantly been added to buildings with very slight possibility of getting good bond to the ends of the party walls, and even in the

building of new premises great difficulty is experienced in making the façades of two adjoining houses meet at the centre line of the party wall, and at the same time getting good bond. Nevertheless, this ought to be done, for we very frequently meet with cases where the walls at this spot are cracked from top to bottom, and are very far from being safe. In case of rebuilding, where a party wall, being exposed, is found to be unsound, it is the duty of the surveyors duly appointed to determine on the steps necessary to be taken in respect of it, and they ought to keep the responsibility from all other parties. Very frequently, where work is being done irregularly, the building owner gives the adjoining owner notice that he will not be responsible for anything that may happen to the adjoining premises; but at least he must have some responsibility for the party wall of which he is joint owner. If neither party will support it, it may result in accident before the attention of the district surveyor is called to it. On the other hand, a building owner who has neglected to give the proper notice in good time, and desires to rebuild a party wall without waiting for the period of three months, is often anxious to get the wall condemned as a dangerous structure, which would operate unfairly to the adjoining owner. One who desires to build a new wall, and to make his neighbour pay half the cost, although the existing wall may be quite good enough for the latter, will also try to obtain the condemnation of the wall, often on very slight grounds. I have now touched upon every part of the Metropolitan Building Act which relates to party walls, except only certain matters of procedure, which are rather in the department of lawyers than in ours. Nevertheless, these portions may be very usefully studied, and the opinion of an experienced lawyer on any difficult case will usually throw great light on any part of the Act. My object has been to arrange the matter in a form to be easily understood, to point out those misapprehensions which seem most prevalent, and to notice some of the cases of difficulty which we meet with in practice. I shall feel glad if those members who have had most experience in these matters will give us the advantage of it, and particularly if they will point out any matters which seem to have been insufficiently noticed, or which require to be corrected; and I trust that the result will be useful to the members of this association.

The PRESIDENT, in inviting discussion, remarked that Mr. Blashill had treated a practical subject in a very clear and lucid manner, and had touched upon several points which had probably escaped general notice.

Mr. ROBERT WALKER feared there was considerable want of knowledge, even amongst metropolitan practitioners, with regard to party walls. In a case in which he was called in, a boiler was built close up to a party wall, and to gain more room the wall was cut into, an arch turned, and part of the boiler fixed in the cavity. When the adjoining owner was reminded of the danger, he replied, "It's only a party wall." Some time since a jury of his countrymen took upon themselves to censure him for allowing what he had no power to prevent, and since then he had condemned some 200 party walls in the district for which he had the honour to be district surveyor. His theory was, that the clause in the Metropolitan Building Act which says that buildings shall be enclosed by walls of a certain thickness makes it compulsory that the building shall have a wall on all four sides, and the next section of the Act seemed to carry out that idea. In this he differed from Mr. Blashill, who thought that an easement could be gained by an adjoining owner in an external wall. Many people, even members of the profession, entertained very erroneous ideas as to the extent of ownership in a party wall and what might be done to it. It was often supposed that a man might deal with the wall as he pleased, and even cut it to pieces so long as he kept on his own side. The respective rights were, in fact, analogous to those of the joint owners of an elephant, one of whom proposed to shoot "his half," but was prevented on the ground that he only possessed an undivided moiety. The Act prohibited a man from even cutting into the chimney breast of the wall. An anomaly in the Act was, that it gave the architect power to do certain work, but no con-

trol over it. The whole responsibility rested with the surveyors called in on either side, and the umpire they selected. As Mr. Blashill had pointed out, if the adjoining owner were cross-grained, he might decline to appoint a surveyor, and the building owner was at a dead-lock. The best course then was either to get a mandamus, or—and this was an alternative he had not yet been able to induce a client to adopt—to make an *ex-parte* application to a judge at chambers. As a district surveyor, if he found the adjoining owner would not move in the matter, he should bring the case before the Metropolitan Board of Works, and so hold him responsible. It was essential in modern building in the City, in which the front and back were often little better than iron and glass structures—especially if, as was often the case, there was an underground railway near by, and sewerage works were going on in the street—that the party wall should be solidly constructed, for it was the backbone of the building. He believed one result of the paper would be to define the law as to party walls, and thus save a great amount of vexation and litigation, and he would propose a vote of thanks to Mr. Blashill.

Mr. GILBERT REDGRAVE called attention to the clear manner in which Mr. Blashill had shown that the third surveyor was not an umpire, as Mr. Walker had said, but could only act conjointly with the two surveyors by whom he was called in, and that the award must be that of two of the surveyors. [Mr. Walker explained that he had only used the word "umpire" in a colloquial sense: all three must act together.] One of the great difficulties of the question was as to the point at which the party wall joined the front wall—where the former stopped in the case of the struts and other ornamental features. He did not know of any decision on the point. In a case of rebuilding where the building owner purposed going to a much greater height than the original structure, and the adjoining owner wished his property to remain unaltered, the party wall must be thickened, and that at the expense of the building owner's land, for the central line of demarcation was shifted to his disadvantage.

Mr. J. D. MATHEWS remarked that every party wall had its own peculiarities, and thus a great number of questions arose which could only be dealt with as they occurred. The Building Act, however, laid down clear general rules for guidance. The raising and altering of party walls was often complicated by claims as to damage to light-easements. A case of the kind was instanced to show the practical difficulty of equitably adjusting these points. Another matter in which a great deal of trouble arose was that in which the Building Act empowered the building owner to do certain work, but not in such a way as to inconvenience adjoining owners. This provision caused great difficulty in building operations in the City, where there might be five or six owners to as many floors, some of whom must necessarily be inconvenienced. Still, it was an open door for litigation, and it would be satisfactory to know what the building owner could do in the matter, and when. Another point not yet touched upon was that of compensation to adjoining owners for inconvenience. The Act did not allow anything, and as several attempts had been made to obtain an award of damages the question was likely to be submitted before long to the law courts for settlement. He trusted it would not be decided against the building owner, for it would prove a very serious impediment to reconstructions. The removal of chimneys was often a very important matter in party-wall alterations. In old buildings blocks of chimneys were often found projecting several feet and resting upon trimmers, and the greatest care was needed to ascertain their relation to one another and to the party wall. He had been engaged in a rebuilding where heavy masses of chimney were set one on either side of timbers through a party-wall, so that in taking down the one block it became necessary to estimate the weight and tie down the beam, so as to counterbalance the weight of the other chimney.

Mr. S. F. CLARKSON considered that so long as the building owner did not affect the adjoining owner's rights in a party wall in the stability of the division, or in his convenience, a considerable amount of work might be done

to the wall, and the Act might, indeed, be strained to a certain extent—say, to the removal of a few bricks, or other reasonable alterations. There was considerable uncertainty as to party-fence walls, and at some future day a court of law might be expected to be asked to define the relative rights and duties in these structures. The Metropolitan Building Act was, as Mr. Mathews said, in the main a good and useful measure. The rights secured to adjoining owners were a mitigated boon, and he believed it would be an admirable thing if its provisions were rendered applicable to the country generally. Notably were its provisions needed for semi-detached villas just without large towns. A general Building Act should not only contain clauses for general stability and protection from fire, but should also prescribe the rights of neighbours in party walls. Further building legislation was about to come into force in London, the Metropolitan Board of Works having under consideration a new code of bye-laws. This would need to be closely watched, for it appeared by an unfortunate wording to sanction the use of inferior bricks for party and the other internal walls.

Mr. HUNTER asked if there was any power in the Building Act to enforce the building owner to carry out the works at the expiration of the three months' notices to the adjoining owners? No allusion had been made as to the state of the law on the formation of openings in a party wall above the level of adjoining premises. If a wash-house or shed adjoined a lofty warehouse, was it inadmissible to open a window in the wall between the two? It seemed that a party wall must be erected between the two, and yet that a window with sills only 18 in. above the parapet might be opened in the warehouse. He thought it would be very difficult for Mr. Blashill to maintain his reading of the Act on this point. Under the Building Act a party wall was not treated from the point of ownership but of separation.

The vote of thanks having been accorded to the lecturer by acclamation Mr. BLASHILL replied to the various points raised. As to the termination of a party wall, he considered that it came to front and back faces of walls, so as to completely separate the two buildings. The question of the true centre line of a party wall was full of difficulties, and should be settled in the courts. As had been pointed out, the wall was often in different thicknesses at the several floors, and those again were held as separate occupations. Adjoining owners had no power to compel action being taken at the expiration of three months' notices; they could be, and often were, renewed again and again. He was concerned in a case in point, in which he had been compelled by circumstances to repeat the notices for seven years, and the adjoining owner had twice died during the interval, and the proposed works were not even now begun.

CAST-IRON PIPES.*

TO all engaged in the design, management, or laying of cast-iron pipes, a small and unpretending brochure, by Mr. Ernest Benedict, C.E., will be found a useful and practical guide. The little book before us is the result of experience in the inspection and testing of pipes which the author has acquired in that capacity. As a rule, we may safely assert that few civil engineers or surveyors have had any but a very superficial acquaintance with cast-iron pipes, the examination and testing of which are generally left to the foreman of works or to the founder himself. Under the head of "Design" some useful hints are given which will be found of especial value to town surveyors and others. As regards the length of pipes they vary from 9 ft. long up to 12 in diameter to 12 ft. long, when of greater size. The author observes, the shorter the pipe the stronger it is, for the joints operate as bands, and he also points out the importance of making sockets strong enough to resist the caulking process required in spigot and faucet pipes. Turned and bored pipes have been used up to 48 in. diameter, and the trench made to receive them is not required to be cut much

* Cast-iron Pipes. By ERNEST BENEDICT, C.E. London: E. and F. N. Spon, Charing-cross.

wider than the pipes; but in laying spigot and faucet pipes the workmen have to get all round the faucet. As regards "collars" for joining spigot ends, the author recommends their being made the depth of three sockets, as they are often used on pipes cut on the spot, and they should be wider than the faucets. Lead joints are advised to be $\frac{1}{4}$ in. thick. The difficulty of testing the thickness of bent pipes makes it necessary they should be cast thicker than straight pipes to ensure a minimum strength. In speaking of connections between service pipes and mains, the author says, the "pap, button, or projection cast on the pipe is the worst, and if a pap is used it should form part of the faucet, for if placed in the middle of pipe it will be a source of weakness to the casting, as any sudden thickening on a straight pipe is apt to draw the metal all round it by reason of the unequal cooling. A ring or band of metal is better. It strengthens the pipe, and no matter what side of the pipe be uppermost, a connection can be made in any direction." Saddles are considered the best and cheapest mode of connection. The formula for thickness is—

$$T = \frac{PR}{C} + K$$

where T = thickness in inches, C = coefficient or ultimate strength of cast iron in pounds per square inch, divided by factor of safety, P = working pressure in pounds per square inch, R = radius in inches, and K = constant in inches, added to resist sudden shocks. Under "Manufacture" we have some desirable suggestions. For instance, as to cores of different sizes and makes, it is very truly said that they come out in rotation as they went in if dried in the same oven, whereas every size of core requires its own time in the oven. If the core be too much or too little dried it scabs, and weak spots in the pipe will be the result, and these are often overlooked. In casting, it is recommended to cast the pipe's socket downwards, so that the socket may be made of metal cast under pressure. In cold or wet weather pipes should remain longer in the "dipping pan." The coating is composed of oil of naphtha, tar, &c., but it will not adhere properly until both the pipe and pickle are of equal temperature. Thin places may be detected by water standing in the pipe when laid level. The usual deviation in thickness allowed is $\frac{1}{16}$ in., but a pipe having a difference of thickness of more than $\frac{1}{16}$ in. at different places should be rejected if the pressure is great. A pipe with unequal sides is found to be weaker than one of the uniform thickness of the thinner side. In regard to the weights of pipes a margin of from 2 to 5 per cent. is generally allowed between the extremes. The writer says it would be more consistent to vary this margin according to the superficies of the pipe, or, say 40lb. for a 10in. pipe 9ft. long, 50lb. for 10in. pipe 12ft. long, and so on. We cannot omit to give the author's advice upon the tests for pressure. The usual test is twice the working pressure, but we quite agree in the remarks that there is no advantage in testing a pipe which it is intended to use afterwards to too high a pressure, for the metal is apt to become strained, and therefore weakened by the process. The best test, says Mr. Benedict, "is to burst a pipe occasionally in the machine—that is to say, go on adding to the pressure until the pipe gives way. This will give a good idea of the ultimate strength of your pipes."

A BUFFET CEILING IN ENAMELLED IRON.

WE have this week seen a very novel kind of ceiling decoration which the well-known firm of art decorators, Messrs. W. B. Simpson and Sons, of St. Martin's-lane, have introduced in the new buffet at the Grosvenor Gallery, Bond-street. The peculiar feature of the ceiling is that it is made of enamelled iron in plates of the size of the panels, and that it presents a clean washable material, well able to resist the deteriorating agencies of smoke, vapour, or gas, while its surface may be decorated or painted in any style of art. The ceiling at Grosvenor Gallery covers a long apartment or buffet, and is divided into panels by longitudinal and transverse beams, the centre

panels being the largest. Each of these divisions are subdivided into smaller panels by white painted moulded ribs of smaller section, with gilded members, and within these are the painted enamelled plates with a highly-vitrified surface. The design is Renaissance in character, and is executed in blue and cream colours, the centre panel figures being relieved on a deep ground of blue with a less depth of tone for the marginal panels. The main beams have a bold fret, and are gilded, and the general tone and effect are highly pleasing and appropriate for a buffet. We understand that the colours are vitrifiable as in china painting, and will resist the action of smoky and other detrimental agencies. The plates are light, can be produced to all ordinary sizes, up to about 8ft. in length, and they can be fixed to ordinary joists or to boarded or concrete ceilings. The side walls of the buffet are divided by pilasters formed of majolica tiles of a cream colour, set in white and gold margins, the compartments between having painted tile borders of a dark sage-green pattern, within which the panels are of plain cream-coloured enamelled tiles. Each compartment is surmounted by a semi-circular panel, in which is an emblematic figure-subject in painted tiles, and the general effect is in keeping with the ceiling. In combination with the tiles we think the enamelled iron decoration of Messrs. Simpson is admirably adapted for restaurants, halls, and galleries, and in every situation where a durable and easily-cleaned kind of decoration is required, and we can recommend it to the profession.

THE GRAND HOTEL, CHARING-CROSS.

WE have in a previous notice referred generally to the architectural features of this important building, and we now take the opportunity of the occasion of a visit to the building last Saturday by the Architectural Association to give a more detailed description of the structure. As our readers are aware, the block of building occupies a very conspicuous frontage towards the Strand and Northumberland-avenue, besides a return down Northumberland-street, and the whole extent of frontage all round is something near 420ft. The two main portions of this frontage are joined by a circular curve of 60ft. radius, and the angle being rather acute between the main fronts, the architects, Messrs. Francis and Saunders, had to exercise some skill in distributing their departments. From a glance at the plans, we are enabled to say much ingenuity has been shown in the economy of the arrangements, the architects having utilised the central area, usually a court-yard in Continental hotels, by a grand saloon or *salle-à-manger*, 96ft. by 50ft. The ground floor, in fact, forms a quadrangle, with the exception of the wing on the Northumberland-avenue side, and its two main fronts have a series of shops, 13 in all, those in the rounded corner radiating in the lines of their division walls below, which are basements, and vaults beneath the pavement. The side towards Northumberland-avenue is devoted to the buffet, which extends about 80ft. from the entrance angle, and is 20ft. wide, above which are the kitchen department and the bath-rooms and closets. The grill-room is in the basement below the buffet. The south wing contains a goods' entrance and staircase, fronting the avenue, a serving-room, and a secondary *salle-à-manger*, while at the south-west angle is the smoking-room and entrance-hall, facing Northumberland-avenue. The hall and inner lobby entrance to the centre saloon with the grand staircase abutting on the west of it, are cleverly planned, so as to obtain rectangularity in the disposition of the marble columns which will adorn this portion, and the secondary *salle-à-manger*, serving-room, and buffet are in convenient proximity. The grand saloon is surrounded by a corridor divided by a range of stanchions, which will ultimately be cased with marble or scagliola to represent Corinthian columns, its central avenue having an arched iron roof of elliptic form, occupying the lower part of the light court in the centre of the blocks above. These stanchions carry, in fact, the back-walls of the building on the upper floors. Ascending by the grand staircase or the passenger lift on

the Avenue side, we reach a spacious landing adorned with detached marble Corinthian columns, which communicates with a surrounding corridor, about 7ft. wide, traversing three sides of the building, and giving access to a suite of bedrooms and sitting-rooms. In the Strand block there are six bedrooms, lighted from centre area, each about 15ft. by 13ft., and 7 sitting and bedrooms in front. The south wing is similarly divided, also the curved frontage towards the Avenue; while on the east side, over the buffet, are a spacious kitchen, with lifts in communication with the larder and bakery departments above, closets and bathrooms for ladies and gentlemen, and two additional staircases. The second and third floor plans repeat this general arrangement, the sitting-rooms and bedrooms being occasionally arranged *en suite*. The passenger lift, about 8ft. square, will communicate from sub-basement to the uppermost floor, and, we understand, will be supplied by the firm of R. Waygood and Co., of Great Dover-street. It is intended to work it by gas power, 2 engines being provided. Altogether there are about 250 bed and sitting-rooms in the five floors above the ground story. A ladies' drawing-room and a library are provided on the avenue side above the smoking-room. The kitchen department is built with fire-proof floors on the well known and well-tried Dennett system. We may add that the basement is devoted entirely to cellars and vaults below the pavements, and these and the shops over will form a large source of revenue. Each shop has its own staircase to the basement, in which is a sink and w.c., and the vaults are lighted by Hyatt's patent lens lights in the pavement in front of every shop. Under smoking-room is a billiard-room. A few details of construction demand notice, and first we may explain the grand staircase, occupying a space of about 25ft. by 19ft. This will be fireproof, being constructed with a concrete core to each step, encased with marble, and we hear that to the clerk of works the principle adopted is due. The principle which has been approved by the architect consists of supporting each step on a rolled flanged joist tailed into the wall. Through these joists are slots for hoop iron to pass through, and the concrete is filled in to encase the iron joists and bars. The steps will have Sicilian marble treads and risers, and the soffit is to be panelled in Parian cement, a trefoil moulding being run on the outer edge. The stairs will be lighted above by a dome light on roof. The Dennett flooring is being constructed for the ground and first floors and kitchen department, Messrs. Bennett having supplied the iron girders. The other floors have 11in. by 3in. joists, pugged between. Ventilating flues are provided in the walls of smoking-room, and the main transverse division walls between the apartments are 18in. and 1ft. 11in. thick, the latter where flues occur. The outside brick walls, exclusive of stone facing, are from 1ft. 11in. to 2ft. 5in. thick, and the building is six stories high. We may mention there is a fall of about 6ft. in the ground from east to west. Iron flanged stanchions, filled up with brick in cement, carry the piers of the main façade. These will be cased in marble slabs between the shops, forming a series of pilasters. The grand saloon we hear is intended to be encased in marble or scagliola, and also the entrance and staircase, but nothing definite has been agreed upon yet. The stone of the main façades above the ground story is of Box-ground, supplied by Messrs. Picton and Sons, and is of excellent quality. We understand Portland has been used up to the ground story cornice. We may add that the elevations of the façade are now considerably advanced, and will be crowned by a Mansard roof and three lofty pavilion roofs. The open light court above *salle-à-manger* is lined with white glazed bricks of excellent quality, supplied by Messrs. Cliff and Sons, also the arches to windows; and the walls generally are built in lias cement, supplied by Messrs. Nelson and Co., the backing to stonework being built in Portland cement. Mr. G. H. Holloway has acted as clerk of works under the architects. Mr. Coates is general foreman, and Mr. J. Woodward foreman of masons under the contractors, Messrs. Merrit and Ashby, of London-wall. The contract is, we believe, about £100,000, exclusive of art decorations.

DESIGN FOR A TOWN HALL—ST. MICHAEL AND ALL ANGELS,
TURNHAM-GREEN—"BUILDING NEWS" CLUB DESIGN
FOR SEMI-DETACHED VILLAS—SEDBERGH SCHOOL—NEW
HOUSE AT PUTNEY-HEATH.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ROYAL ACADEMY TRAVELLING STUDENTSHIP
DESIGN FOR TOWN HALL.

We have already published* the prize design in this competition, and we publish to-day the principal elevation and plans of the design submitted by Mr. R. W. Gibson, which certainly ran the one selected very hard in the race. Our readers may now compare the two designs—each of which will furnish much that is suggestive. The author has endeavoured to obtain a monumental character, constructionally truthful and undisguised. Classic forms are freely but appropriately adapted in the details, while the use of such anomalies as attached or superimposed orders, or two-storied pilasters, is carefully avoided. The site was described as fronting a public square or garden: the building would therefore be viewed from considerable distances. The plans provide the accommodation on basement, ground, and first-floors, as required. No mention being made of other stories, the author supposed the design was limited to these. The assembly-room is placed in the centre of the site, surrounded by a wide corridor connecting the various departments. These, although not altogether under different roofs, are so arranged that each is distinct and separable from the others. Yards are provided at the back for prison vans, fire-escape, &c. As we before remarked, the limited time in which these designs have to be prepared does not allow of very mature deliberation or study.

"BUILDING NEWS" DESIGNING CLUB.
SEMI-DETACHED VILLAS.

PROBABLY one of the most difficult problems which an architect has to solve in every day practice is to design an inexpensive and appropriately treated pair of semi-detached villas, which shall comprise ample apartments and accommodation, with compactness of plan, and so designed to be suitable for erection on a series of plots of limited frontage. That suburban villas as a rule are among the most vulgar and badly contrived buildings to be met with is amply proved by those seen in the suburbs of every large town in the three kingdoms, and with the idea of helping forward the few efforts which have already been made to improve matters in this respect we chose the subject of a pair of villas, such as are constantly required as a subject for the members of the BUILDING NEWS Designing Club. To-day we publish the design which we have selected from about 30 plans sent us; and, although we cannot deny that there are several parts, chiefly in the hall, staircase, and kitchen, which might be considerably improved upon, as we pointed out when reviewing the series, yet as a whole the plan offers much that is worthy of imitation; while the architectural treatment is suitable and good. The difficulty of overlooking has been provided against but partially, as the window and door of the sculleries would immediately overlook those of the adjoining houses, which is an objection.

* BUILDING NEWS, Jan. 3rd, 1879.

NEW HOUSE, PUTNEY-HEATH.

THE building which we illustrate this week is erected on the site of one of the old Government semaphores, which, before the invention of the telegraph, connected Portsmouth Dockyard with the Admiralty at Whitehall, and, weather permitting, signalled a short message in about 20 minutes. The new house being placed on such an elevated spot commands extensive views, and harmonises extremely well with the landscape. The rich full red tone of the walls and the Broseley tiles of roof, relieved with stone, look extremely picturesque on the wide expanse of heath. The ground plan which we give shows the general arrangement of rooms, all of which are well proportioned, the woodwork of drawing-room being Spanish mahogany, the drawing-room decorated in colour, and the remainder of floor and staircase finished in wainscot. The basement, which is kept above the garden level, is lofty, and provides a spacious billiard-room and school-room, with kitchen and numerous offices. On the upper floors there are ten bedrooms, with dressing and bath rooms, &c. The whole of the works have been carried out by Mr. Robert Avis, of Putney; Mr. Theodore K. Green, of Finsbury-place, being the architect.

SEDBERGH SCHOOL.

THE ancient Grammar School of Sedbergh has, like many others in the country, lately come under the Endowed School Commissioners. A new "scheme" has been drawn up, and under the guidance of a large and influential board of governors new life is being infused into the old school. A head-master's boarding-house for 40 boys was completed last autumn, and a second boarding-house for the same number of boys will be finished next autumn. The illustration gives a view of the proposed "central block," containing various class-rooms, physical science rooms and laboratory, drawing-room, governor's and master's rooms, large hall for assembly, chapel, &c., and, when completed, will form a conspicuous group of buildings occupying a commanding site to the west of the town. At present only the group of class-rooms are being built. The stone for the buildings is procured from quarries near Shap. The roofs are covered with green Westmoreland slates. Messrs. Paley and Austin, of Lancaster, are the architects.

CHURCH OF ST. MICHAEL AND ALL ANGELS,
BEDFORD—ARK ESTATE, W.

DURING the last fortnight we have published the geometrical drawings, with details, of this new building, and to-day we complete the series by giving a perspective view with the general ground plan. Another page is devoted to the longitudinal section and details of the aisle windows with buttresses. The houses and poplars in the Woodstock-road are correctly shown in the view, from a sketch taken on the spot for the purpose. To the west of the church is an open common, bounded on the north by the trees seen in the picture. All the old trees on the estate are left standing, and fresh ones have been thickly planted. Mr. R. Norman Shaw, R.A., is the architect.

ARCHITECTURAL & ARCHAEOLOGICAL
SOCIETIES.

DERBYSHIRE ARCHAEOLOGICAL SOCIETY.—The first annual meeting of the Derbyshire Archaeological and Natural History Society was held at Derby on Monday. The first volume of "Transactions" was issued, the most important part of which is a full report of the society's excavations at Dale Abbey, which will be resumed in the spring. One of the illustrations to this paper is of a stone effigy of 13th century date, found nearly perfect in the chapter-house. Mr. Bloxam pronounces this effigy of a canon to be in many respects absolutely unique. The volume has other interesting papers on Derbyshire archaeology by C. S. Greaves, Q.C., J. Charles Cox, W. H. St. John Hope, W. H. Hart, F.S.A., &c.

LEEDS ARCHITECTURAL ASSOCIATION.—At a meeting of this association held on Thursday week, a paper on "Elizabethan Architecture" was read by Mr. W. H. Thorp. Mr. Thorp described the decline of Gothic architecture in the reign of Henry VIII., and made reference to the characteristics and features of the Per-

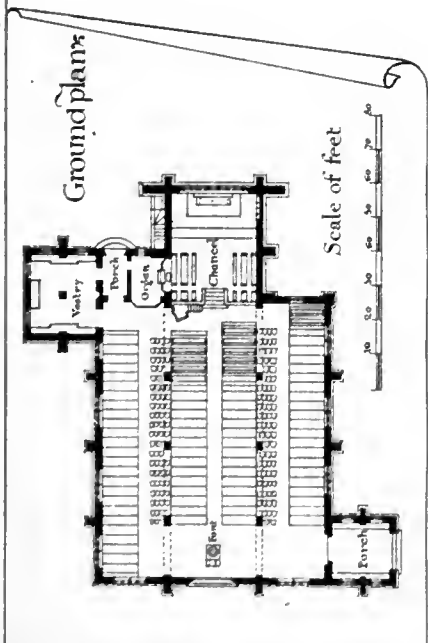

pendicular or Tudor style of architecture in vogue during the earlier years of his reign and that of his immediate ancestors. The introduction of classical architecture in the reign of Elizabeth was treated upon, mention being made of the causes for the change in style, the chief ones being the example set to us by the other countries of Western Europe, who had adopted the classical styles nearly one hundred years previously; and also the teaching of classical literature in our colleges, the arts always following in the train of, and being largely influenced by, the literature of the time. The latter holds equally good now, and in reference to it Mr. Thorp said—The literary works of note now so abundant, dealing with nearly every subject and thing under the sun, accounted to a large degree for the diversity of taste and style in things architectural; the Japanese motifs in design, now so much in vogue, to a large extent owing their existence to books upon the Japanese and Chinese peoples, their buildings, manners, and customs, and the large importations into this country of their goods—such as cabinets, lacquer work, porcelain, silks, and fans. It was stated that very few churches are left to us of the Renaissance period—St. John's Church, in Leeds, being one of the best examples erected in the reign of Charles I., the interior having a grace and beauty, an antique and old-world appearance, and a quiet harmony of colour denied to many other ecclesiastical buildings of greater importance. The examples of secular or domestic work are infinitely more numerous than those of churches—the palatial halls of Longleat, Wollaton, Hardwicke, Haddon, and Holland House, and also some of the colleges of Oxford and Cambridge being described, with mention of their architects. Mr. Thorp, in conclusion, said that he considered Elizabethan architecture had been unjustly condemned, for it was the natural outcome of the age, and was well adapted for the wants and requirements of the sixteenth century.

NORTHERN ARCHITECTURAL ASSOCIATION.—On Thursday, the 23rd inst., a special meeting of the Northern Architectural Association was held in the Old Castle, Newcastle-on-Tyne, for the purpose of presenting a farewell address and a purse of sovereigns to Mr. Robert Lamb, of Darlington, who is about to leave England for New Zealand, on account of his health. The chair was occupied by Mr. Thomas Oliver, president of the association, who also made the presentation. He referred to Mr. Lamb's connection with the association, which was formed just twenty-one years ago, and regretted the cause which led to his removal to a distant clime, although he firmly believed that the qualities which he knew from experience Mr. Lamb to be endowed with were the very qualities suited for a new country. He was sure that every member of the association, in wishing Mr. Lamb farewell, also wished him God-speed. The address, which was very beautifully illuminated and framed, was then presented along with the purse of sovereigns. Mr. Lamb thanked the meeting for the kindness that had been exhibited towards him, and the proceedings then terminated.

SCHOOLS OF ART.

CIRENCESTER.—The annual distribution of prizes took place on Wednesday week. The reports showed that there were now 103 students. At the national competition at South Kensington a Queen's prize and a third-grade prize were gained by students for designs for a ceiling in plaster work. One South Kensington and three local scholarships and five other third-grade prizes had been also awarded to Cirencester by the Department. A number of local prizes had been awarded—Mr. Kemp, head-master of the Gloucester School of Art, being the examiner. After the presentation of prizes and certificates, a vote of thanks was passed to Mr. Miller, the head-master.

The Royal Albert Hall lies in the very heart of aristocratic London. There is not a mean dwelling within half a mile of it, and that is the especial reason why her Majesty's commissioners, who have turned it into a picture gallery, charge only sixpence for admission. The last attempt to utilise the poor colosseum of Kensington Gore will be as big a failure as every other effort to use the royal folly.

R. NORMAN SHAW R.A.
ARCHITECT

A SCIENTIFIC AND SAFE WATER-CLOSET.

AT page 651 of the *BUILDING NEWS* for November 27th, 1874, you published a letter from me under the above heading, and with a sketch, showing my then ideas of the requirements for the safe fitting up of water-closets. That sketch was open to improvement, and in a few months was developed into my patent of April, 1875, which patent, according to page 408 of Mr. Baldwin Latham's "Sanitary Engineering," is the same system as that afterwards mentioned in the Model Bye-laws of the Local Government Board. It is difficult to arrive at perfection, however, and all the above systems left room for improvement. As another contribution towards that improvement, I beg to show a sketch of a style of fitting up a water-closet, either with or without a lead siphon trap,* which, for combined safety, efficiency, and simplicity, is, I think, in advance of any plan yet published.

The novelty or speciality in it, the open pipe, A, in the sketch, was suggested

the water-closet. This is effected as shown in sketch. C is one of my ventilating drain-traps, but any other suitable one may be used as the plan is not patented, and is freely open to be adopted by any one. D is the fresh-air entrance channel to the trap and soil-pipe, E. This soil-pipe, E, being surmounted by a 4in. ventilator, K, when wished, a constant current of air is expected, and will generally be found to be passing up the soil-pipe. This up current will tend to draw in air from the open channel at A, at the end nearest the soil-pipe; while, if an opening existed in the branch soil-pipe, E', no bad air from the upright soil-pipe would get access to the house, but only through the short portion of branch soil-pipe, about 2ft. long or so, fresh air pouring in from the end of A nearest the water-closet. Again, owing to the ventilating pipe, H, no bad air could gather in the branch soil-pipe. B is a swinging valve, that might be put in if wished of tinned copper, but I consider it unnecessary. M is a Bramah valve-closet, but other closets may be used. N is the lead safe, with safe-pipe, T, carried outside, and with hinged valve at its outlet

to me by a perusal, about eighteen months or so ago, of the article on "Sanitary Science" in Blackie's "Encyclopædia," by Dr. Robert Bell, F.F.P.S., Glasgow. I never, however, worked the idea out thoroughly until last week; but, having once done so, I believe the idea to be not only very good, but easily carried out in practice, and especially in new houses. The intention, in 1874, was to lock off the drain from the soil-pipe and water-closet; but the intention now is to keep out as far as possible any gas that may be bred in even the soil-pipe itself from

end. R is the level of the floor; Q is the water-closet window; S is a ventilating shaft for the water-closet enclosure, which may be surmounted by a ventilator. Only one water-closet is shown leading into the upright soil-pipe, but several may be led into it, as in flatted houses or large private houses, and by carrying each branch soil-pipe, say, 3ft. or so along the wall, and leaving about 2ft. of it open at the top, as shown in section at A of the sketch, then each water-closet is locked off from the soil-pipe, so far as the passage back of sewage gas into it is concerned, without interfering with the free passage outwards of the water and soil. J is the soil-pipe continued upwards above the roof, full diameter; L is a rain-water pipe, which in some cases may, with perfect propriety, be led into it, especially if no windows are near. Its worst effect is to tend to supply the ventilator with air instead of the air being forced to come from lower down. It is only ticked in as a suggestion, however, and people can please themselves.

As above stated, the idea or plan, which can also serve for waste pipes, is not patented and

I shall be glad to hear of its adoption anywhere, and in the meantime will be pleased to hear the opinion of architects, practical sanitarians, or others interested in sanitary progress.

W. P. BUCHAN, Sanitary Engineer.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary meeting of the Institute was held on Monday evening; the President, Mr. Charles Barry, in the chair. The following gentlemen were elected to membership:—As Fellows: Henry David Davis, associate, Finsbury-circus, E.C.; and Henry Walker, associate, South-parade, Leeds. As Associates: Charles Grieve, Park-villas, Shepherd's-bush, W.; William Henry Wood, Guildford-street, Russell-square, W.C.; Robert Curwen, jun., South Castle-street, Liverpool; Charles William Brooks, Duke-street, Adelphi, W.C.; and Alfred Hessel Tiltman, Great James-street, Bedford-row, W.C. As Honorary Associates: Richard Fuge Grantham, Assoc. Inst. C.E., Whitehall-place, S.W.; Henry Bessemer, M. Inst. C.E., Denmark-hill, S.E.; and William Robert Wood, Carlisle House, Brighton.

An application from Mr. Augustus Laver, now a naturalised American citizen, residing at San Francisco, to be transferred from the list of fellows to that of hon. and corr. foreign members, was read by the Secretary. The President stated that Mr. Laver was with them that evening, but would leave in the course of five-and-thirty minutes for the United States. He had since 1865 been a fellow, and as it would be desirable to maintain a knowledge of what was going on in America, he should ask permission, in breach of the bye-laws, to propose Mr. Laver's election that evening. This was carried by acclamation, and Mr. Laver was cordially welcomed.

The Secretary announced several donations to the library, including a new architectural work by M. Leueur, entitled "Histoire et Théorie de l'Architecture." Mr. PENROSE said the last-mentioned was a valuable work, but the author had fallen into error in attributing the horizontal curves in Greek architecture to defective foundations.

The President said he had to make a mournful announcement—that of the death of a distinguished Frenchman, M. Joseph Louis Duc, the architect of the Palais de Justice, who only two years ago came over to receive the gold medal of the Institute. Prof. Donaldson had undertaken to draw up a letter of condolence to the widow, and an expression of regret at the loss architecture had sustained. He had further to announce that Mr. Thomas Henry Wyatt had consented to take the late Mr. Cockerell's place as hon. corresponding secretary until the next general election, and that the council had accepted the offer with thanks. At the close of the next meeting a special meeting would be held for the purpose of confirming the temporary appointment.

THE MODERN RESTAURANT.

The President said Mr. Verity's paper was now open for discussion. He regretted that he was unable to form one of the party who visited the Criterion on the previous Monday.

Mr. W. M. TEULON, as one of those who went over the Criterion, wished to express his appreciation of the economy of space observed in its planning and arrangements, and the ingenuity of the heating and ventilating apparatus. The decorations were also good.

No other member rising to continue the discussion, the President suggested that perhaps all the members were so well qualified for practice, that they believed they could each have met the difficulties with which the undertaking abounded in the best possible manner—when the way was pointed out—and that they could have found a remedy for all the defects. Still, there must have been more than one mode of meeting some of the difficulties, and he wished some member had indicated some other method. He was struck with the extreme ingenuity with which so many different elements were combined in one building. He noticed that a kitchen was provided on every floor instead of concentrating the cooking apparatus at the top of the building as was usual; had this complicated arrangement been found to work with-

* I have still a strong fancy for the retention of the siphon trap, and since writing the above I happened to call upon Mr. James Maclear, managing partner of St. Rolox Chemical Works, who is experimenting with water traps. He easily got the gases to pass through the water, but failed in all his attempts to get ferment germs to pass through. He hopes yet to manage the latter, but his failures hitherto show the value of water in keeping back germs and disease-breeders from the house or inner side of a water trap. The molecules of the gases may pass freely through between the molecules of the water, and the more readily in imperfectly ventilated pipes, but the germs, being many times larger, cannot get through in the same way, I consider.

out confusion of service and accounts? They had been told that the building cost 2s. per foot, including all that the architect supplied; had Mr. Verity any objection to state the absolute cost?

Mr. C. FOWLER asked as to the weight per foot super. upon the foundations.

Mr. VERITY replied that it was at first intended to have separate kitchens on each floor, but practically there were but three in use—those in basement, principal floor, and at the top, and those for different purposes; the other rooms were subsidiary, and used for serving. The cost mentioned included the construction and engineering, heating and ventilating, but not that portion of the furnishing undertaken by the proprietors. He had not estimated the weight of building, except that portion supported on stanchions.

NOTES ON ST. PAUL'S CATHEDRAL.

Mr. FRANCIS C. PENROSE, M.A., read the following paper on the cathedral of which he has for many years been the surveyor. The subject matter of the notes was arranged under the following heads:—Firstly, the improvements in the crypt, and intimately connected with these the discovery of important records of Old St. Paul's; secondly, the proposed alterations in the churchyard by agreements between the Dean and Chapter and the Corporation of the City of London; thirdly, the new peal of bells; and fourthly, a statement of the position in which the decoration scheme is at present. For the last seven years or thereabouts, said the author, the dean and chapter have endeavoured to make the crypt both useful for ecclesiastical purposes and more worthy as the burying-place of illustrious public characters and artists than formerly. Until lately only a small part has been shown to the public, and with the exception of the immediate centre, containing the tomb of Lord Nelson, and the contiguous chamber, in which the sarcophagus of the Duke of Wellington is placed, it was dark and uncared for. Much of it was devoted to stowage of materials, a large portion of these being the scaffoldings which were used for the school children's festival, and the remainder serving for various necessary purposes. Now, with the exception of these last, the whole has been formed into a *campo-santo*. The walls have been cleared of the soot of generations, and the floor is being laid down with mosaic tesserae in various colours and of classical design. About 4,000 square feet have already been so treated, 3,000 more are decided on, but not yet executed, and by degrees the rest will follow. The eastern part—viz., the site of the ancient chapel of St. Faith—has been arranged for divine service. Around this part of the crypt have been arranged the remains of certain monumental effigies which were rescued from the old cathedral, and which Dugdale's accurate views, taken before the Fire, enabled us to identify. They have each been mounted on a simple altar tomb with the name inscribed. They record names well known in the 16th century—viz., Hewett, Collayne, Hatton, Heneage, Wolley, Baskerville, and some others. The central nave in the crypt has now been opened for its full length of about 450ft., and the bronze car which conveyed the body of the Duke of Wellington to the cathedral in November, 1852, and which for a number of years occupied a chamber near the centre, and terminated the part shown to the public, has been removed to the extreme west. This central portion of the nave is now divided from the side aisles, to which, with the transepts, the workshops and stores are relegated by wrought-iron railing. It was the opening of the western crypt that led directly to the discovery of the remains of Old St. Paul's. One of the arches contained our huge gas-meter, which entirely blocked it up. It was essential that this should be removed, and a pit was dug for it on the outside to the south of nave, to a depth of about 10ft. from the ground line of the churchyard. Just on the edge of this pit, and about 9ft. from the surface, was found a piece of stonework evidently *in situ*, which had clearly some connection with the old fabric. The mortar was different from that used by Sir Christopher Wren, and from its position it could have nothing to do with his work. There was em-

bedded in it the frustum of a column, apparently Norman, from which it seemed that this piece of foundation belonged to some of the 14th century work, and that the Norman fragment was old material derived from the original choir, or perhaps from St. Faith's Church, demolished in 1256. This find then seemed a relic of old St. Paul's. In my office was a copy of the plan contained amongst the Wren collection in All Souls' Library, Oxford, which represents the new cathedral placed upon the old,* and from this plan I assumed I had hit upon the foundation of one of the piers of the passage leading from the cloister into the chapter-house. Guided by the plan, I sank a pit more to the westwards, to try for one of the buttresses of the chapter-house, but with no result. The earth showed no signs of ever having been disturbed. I then tried backwards towards the east, thinking that I might at last get hold of another part of the cloister. The plan again proved fruitless; but a little more burrowing towards the east revealed a fragment of what I thought might be a buttress of the main transept wall—that is the western wall of the south transept. This was about the same depth below the surface as the first discovered fragment; and the next morning part of the cloister wall, with its buttresses, was found, and the S.E. internal angle soon followed. Two of the great buttresses of the chapter-house rewarded further investigation, but these were all, for the other buttresses of the chapter-house had been entirely rooted up, partly for the requirements of the new structure and partly for the drains. We also found the external S.E. angle of the cloister and part of the street wall, and the internal S.W. angle and some traces of corresponding external angle. The pavement in several places exists, composed of squares and lozenges of Purbeck marble, and is about 14ft. below that of the present cathedral, but very nearly on a level with the street to the south. These remains belong to the lower story of what Sir Christopher Wren has described as "a chapter-house of a more elegant Gothic manner with a cloyster of two stories high." The historians of the cathedral inform us that the chapter-house was begun to be built in 1332; but when we study the detail of the mouldings, which are very small and refined, it is impossible to attribute so early a date. Nevertheless, both Hollar's view and some remains of tracery dug up during the excavations point to a general design which would almost fit in with the period assigned. The probability is that the work is actually of the end of the 14th century, but that an earlier design had, with some modifications, been carried out. The vaulting of the chapter-house, although the building was octagonal, was arranged (in the lower story at any rate) so as to rest upon four central columns. This is shown in all the plans; and the base of the middle vaulting shaft is curiously separated from the others which follow the octagonal arrangement for this purpose. All the chapter-house shafts and bases are of Caen stone, but those of the cloister are of Purbeck marble. All are extremely well cut and elegantly profiled. Fearing the effects of frost upon this newly-opened masonry, I had them twice coated with beeswax dissolved in spirits of turpentine, and thus far they have well resisted the action of the weather, whilst some stones of the same material, which, not being *in situ*, were left to themselves, have been much affected by it. When our discoveries are compared with the Oxford plan, there is found to be an error both southwards and eastwards, amounting to about 10ft. in each direction. In other respects the cloister is accurately blocked out, and the length and breadth are in very close agreement with the dimensions. It is a matter of very great interest to ascertain, if possible, whether the plan must be given up as hopelessly inaccurate to at least the above extent, or whether there may not be an occult reason for the particular error, which does not vitiate the plan altogether. A plan of the existing cathedral from measurements to the same scale as the Oxford

plan, shows that the two agree very well indeed. This is, presumably, in its favour. Then we have to consider what was the object of this particular plan; not the detail of the architecture, which is merely sketched on the plan, but the exhibition of the divergence of the axial lines of the two buildings. There are great peculiarities about this plan, which, unless proved to be carelessness, must have an important meaning. The line which is shown for the west front is very considerably out of square with that which is given as the axis of the cathedral; neither is the axis of the transept square with it. The latter is shown as almost parallel to the west front. The east end, again, is an oblique line. Let us compare this plan with other plans of old St. Paul's. The plan is very nearly to the same scale as that given by Dugdale, engraved by Hollar, but there are some differences which show it to be an independent document. There is also among the All Souls Wren Collection drawings a larger plan on vellum, but it is not itself original, and the following account of its authorship has been given me:—"The plan is on vellum, and Elmes, in his 'Catalogue of Wren's Drawings,' says of it: 'Mr. Gutch tells me that Mr. Buckler copied it for Sir H. Englefield.' " Nevertheless, it seems from the above to have been copied from something else, perhaps from an old plan which was falling to pieces, and it certainly represents the cloister and chapter-house with great accuracy. I will call this the "Oxford Plan No. 2." There is also a small-scale plan, engraved by Loggan, and published by Thomas Bowles, St. Paul's churchyard, about 1714, but I think the engraving itself must be considerably older. Thus we have, at any rate, four plans to refer to, and there is the tradition preserved by Stow that the old cathedral was 690ft. long. This statement Mr. Ferrey has discussed at length in his contribution to "The Three Cathedrals," and I think has very justly come to the conclusion that the first figure is in error, and that the proper statement should have been DXC. instead of DCXC. This extreme length is at variance with all the plans, although some approach to it is made in the Oxford Plan No. 2, which appears to give the length of 660ft. The discovery of the cloister enables the scales put upon these drawings to be tested, and they do not any of them bear the test very well. The Oxford Plan No. 1, however—that which shows the two cathedrals—when a proper scale is made for it, from the full length of 507ft., that is from the extremity of the present apse to the western towers inclusive, shows exactly the proper measure for the south wall of the cloister, which is a strong presumption in favour of the general correctness of the drawing, excepting as to the scale, which may have been added by a different hand. The simplest test which can be applied to the plans in comparing them *inter se*, is that of the proportion between nave and choir taken from centre of tower. These are the results:—

	Nave.	Choir.
Hollar's plan ...	1,000	904
Oxford plan, No. 1 ...	1,000	880
" " No. 2 ...	1,000	998
The small plan ...	1,000	962

There are thus two pairs which hold together pretty fairly, Hollar's and the Oxford No. 1, in giving mean proportion of 1,000 to less than 900, and two others give a much larger proportion. There are a considerable number of perspective views extant, and if we examine these together (however divergent they may be among themselves) the mean result may be used to check the plans. Dugdale gives two. The same engraved sheet which contains Loggan's plan gives three. These results are here tabulated:—

	Nave.	Choir.
Dugdale—North ...	1,000	795
Dugdale—South ...	1,000	785
Loggan—North ...	1,000	752
Loggan—South ...	1,000	917
And to a smaller scale on the same sheet—South ...	1,000	890
Mean ...	1,000	828

My object in this investigation is to establish the probability of the Oxford Plan, No. 1, being

* A reduced copy of this plan is published in Mr. Longman's work, "The Three Cathedrals," and was reproduced in the BUILDING NEWS at the time of our review, Aug. 8, 1873—Vol. XXV., p. 159; see also views of old St. Paul's, pp. 88, 135, 138, of same volume, published July 25 and Aug. 8, 1873.

trustworthy, and the evidence of the perspective views is, as far as is goes, in favour of this probability, in reducing the ratio of the length of the nave to that of the choir. Another argument in its favour is that the extent of our churchyard to the east is exactly the difference of length shown between the old and new cathedral on the plan. And in the account of Sir Christopher Wren's works in the "Parentalia," it is stated that the commissioners for rebuilding the City had settled and had obtained Parliamentary sanction for the width of all the streets before anything had been fully determined about the design for the new fabric. It seems, therefore, extremely probable that the street defines most accurately the extent of the old cathedral, and this is again in favour of the Oxford Plan, No. 1.

(To be concluded next week.)

ROYAL ACADEMY LECTURES ON ARCHITECTURE.

THE first of this year's lectures at the Royal Academy was delivered last night by Prof. E. M. Barry. The subjects dealt with were Recent Artistic Losses, the Gothic Revival, and the late Sir Gilbert Scott. After a tribute to the memory of Sir Gilbert Scott and Mr. Sydney Smirke, Prof. Barry proceeded to review at considerable length the career and character of the late President of the Academy, Sir Francis Grant. He said:—"Of the position in the artist world which will ultimately be assigned by posterity to Sir Francis Grant it would be presumptuous in me to speak. This is not the place for such a discussion, nor am I the person to pursue it. We cannot anticipate that calm inexorable verdict which, sooner or later, is passed upon us all, when we have ceased to play our small part in the world's history. There are personal qualities, however, which contemporaries alone can fully appreciate, and which bring home to us the loss of the individual man we have known and respected, and who but lately was a part, so to speak, of ourselves. Every one knows how gracefully, and with what dignity our late president discharged those duties of his high position which came under the public notice; but those who were brought into frequent contact with him, in regard to the daily business of the Academy, can alone appreciate, to their fullest extent, the finer qualities of his nature and culture. The head of an artistic commonwealth, composed of members with the strong idiosyncracies of individual tastes and genius, the aim of Sir F. Grant was ever to govern with his brethren, and not against them. His sway was that of the mild and excellent constitutional sovereign, and had nothing in common with the sternness of dictatorship. His proudest boast was that he left every member of the Academy a friend, and never, I believe, did he express a truer sentiment."

The life of Sir Francis Grant was another instance of the fact that a real love for their calling was a necessity for all true artists. "An inborn aptitude and love for his art," said Professor Barry, "is at least as necessary for the architect as for the painter or the sculptor, and I advise no young man to adopt the profession without it. The art of the giants of the past, whether of classical or mediæval days, must not be degraded in our hands, and be followed as a mere trade, one method among many of obtaining an honest livelihood. The true architect must ever be an amateur in the highest sense of the word; he must, indeed, be an expert in the science of his work, but he must also have love of his work, and taste to appreciate everything that can claim a place in the advancement of art. Those of you who have had the privilege of attending the annual discourses of our late president, on the recurring occasions of the distribution of prizes, will remember how earnestly he advocated the study of nature on the one hand, and on the other an affectionate reverence for the great masterpieces of antiquity. These lessons, although primarily addressed to the painter students, have, nevertheless, a special value to the architect. Our art is, indeed, traditional to the greatest possible extent, so that the task of the modern architect is development rather than

invention. We can afford, therefore, less than other artists to despise the past and rely on ourselves alone. Lasting fame is not easily acquired, and when a building or other work of art has received the admiration of centuries we may be sure that it merits our respectful consideration."

OUR COMMONPLACE COLUMN.

FONT COVER.

FOR some generations after the removal of the font from a baptistery to a position just within the west entrance of the church the earlier situation was recognised by erecting above the font a canopy of stone, supported on pillars or shafts. In the 14th and 15th centuries this gave place to a wooden cover, of which many examples remain in East Anglia. They are pyramidal or spire-shaped, generally octagonal, and rise from four to eight or even ten feet in height. They are usually constructed of oak, richly carved with shallow mouldings, panelled faces, crocketed angles, and end in a bosky finial. The lower portion of two of the sides open on hinges triptych-wise, to allow the rite to be performed—an indication that the more ancient method of baptism by immersion had been abandoned at the time of the addition of these covers to the fonts. In a few rare and late instances the cover more resembles a sounding-board, and like it is suspended by a chain from the roof. Examples of font-covers may be noted at Sudbury, St. Gregory's, a rich 15th century tabernacle, well carved, with evident traces of gilding, vermillion, and blue in the frets (modern font); Ipswich, St. Matthew's, and several other churches; Ufford - by - Woodbridge, pelican terminal to large and open cover; Fingringhoe, near Colchester, small, opening with three leaves; North Walsham; Trunch, a cover gilt and coloured, supported on six wooden columns outside font; and Worstead. During the congress of the British Archaeological Association last year we examined a series of Elizabethan and Early Jacobean covers in the group of churches in the Walsoken district. Of these that at Terrington St. Clement's, was the most noteworthy. It is of great size, has been decorated inside and without with black and white, red and brown, and gilding, with some Scriptural scenes. That at West Walton is of debased Gothic character, and that at Walpole St. Peter is a larger structure in four stages, each face pierced with circular and lattice-like openings. It is worth careful study as one of the few dated examples—1627. From the journal of the notorious Parliamentary visitor, William Dowsing, of Stratford, we learn that he destroyed the cover of the font of the church of St. Edmund, Southwold, and if equal in treatment to the other woodwork of this church the loss thus occasioned has indeed been great. A few of the more remote great 15th century churches near this decayed fishing borough retain their font covers.—EDWARD W. PIPER.

FOOTINGS

Are introduced at the base of walls so as to obtain a larger bearing surface for the support of superstructure. The spread given will depend on the nature of foundations and the weight of walling. With a good firm bed of gravel for a foundation, after carefully bottoming the trenches, the lowest course of footings may be laid on the gravel, making it equal to twice the thickness of wall, the trench being about 6in. wider to allow for working room. In brickwork this thickness is reduced by $\frac{1}{2}$ -brick offsets on either side, at every course, or every second course, according to the depth of trench. In stonework large stones, with a good bearing surface, should be used. In no case should the depth of footings be less than half the thickness of wall. In friable earthy soil a bed of concrete is usually introduced to support the footings, varying in depth according to nature of material used and weight of building, the width being equal to width of trench, allowing working room for footings. Where a good bed of concrete is put in, the usual spread given to footings may be dispensed with. When solidly bedded, footings of ordinary building stones or hard burnt stocks are seldom weighted up to the load they will bear with safety. Concrete in foundations

with good lias lime or cement may be considered almost equal to stock bricks, and will support a load of from 20 to 40 tons per foot superficial before fracture; 1-tenth of this is usually considered the safe load, but one-half may be taken with safety when in foundations if well supported.—C.W.

FORMERET.

The term applied to the rib in Gothic groining which is close to the wall, and which is, therefore, of less space than the other ribs. See Groining.

FOUNDATIONS.

There are two sources of failure which must be guarded against—viz., inequality of settlement and the lateral escape of the supporting material. To obviate the former it is necessary to drain the site, and to excavate all the loose material, filling up with concrete. In clay soils, fissures often occur due to dryness, and it is safest in such cases to lay the footings of wall below the depth at which the weather affects the soil, usually about 3ft. Blue shale is treacherous on this account. When dry, or when the ground is first opened, it is as hard as rock, but a few hours' exposure causes it to slake or run to sludge. One great principle to which recourse may be had is to extend the bearing surface of the foundation. This may be done in several ways: 1, by a layer of stones or planks or a combination of timber and stones; 2, by brick footings; 3, by concrete; 4, by inserted arches. Timber is objectionable when it cannot be maintained either uniformly dry or wet, and the best plan is to form a wide base of concrete, which, if properly consolidated, forms a beam upon which the wall settles evenly. *Concrete foundations:* Gravel ballast or broken stone may be employed, and a certain quantity of sand or chips. No stone should exceed a hen's egg in size. The lime is generally used ground and hot, and is mixed with the stones by turning the mass round by the shovel till the components are well incorporated. The proportion of mixture is generally 6 of ballast to 1 of lime. The concrete thus prepared is either thrown into the trenches from stages 6 to 8ft. above, or rammed in layers of 1ft. to 6in. The last plan is recommended as the best. Hydraulic lime is to be preferred, as the blue lias, or Portland cement (see art. Concrete) may be used. A second source of failure is in the lateral escape of the supporting material as when building on running sand or soft clay, which would ooze out below under a heavy weight. In addition to a concrete base of sufficient width, the area of a foundation in such a case should be enclosed with sheet piling. Where there is a hard stratum below, wooden piles shod with iron may be driven down, the heads cut off to a level, and the wall commenced on a timber platform.

"J. A." says:—"When a firm foundation is required where no firm bottom can be found within an available depth, piles are driven to consolidate the mass a few feet below the area of foundation, which is surrounded by a row of sheet piling to prevent the escape of the soil; the space between the pile heads is then filled to the depth of several feet with stones and concrete, and the whole is covered with a timber platform. Concrete composed of gravel or shingle and hot lime is often used to form a solid bearing for the footings of foundations. Instead of driving piles into soft ground it is considered better to bore holes in the ground, and well fill them with sand, which, from its property of acting almost as a fluid, is more valuable for distributing pressure over a large surface. In many soils, where the ground is too soft for the weight of the walls of the building, it is very effective to dig wide trenches, and fill them with dry sand; this has been sometimes found better than timber planking, concrete, &c. The breadth of a substructure should be proportioned to the weight of the superstructure. Nicholson, in his 'Architectural Dictionary,' says: 'If the texture of the ground is supposed to be constant, and the materials of the same specific gravity, the breadth of the foundation will be as the area of the vertical section passing through the line on which the breadth is measured.' Probably after rock the best natural soil is a compact or sandy gravel."

"C. P. E." writes:—"The suggestions and instructions issued by the Incorporated Church Building Society say: 'To be surrounded, if requisite, by good covered drains. If the soil wants firmness the walls may often be better secured from partial settlements by spreading the foundations on each side, than by deepening or resorting to more expensive works. In all irregular or doubtful soils concrete is recommended for the foundations in preference to any other material.'"

FRENCH CASEMENTS

May be constructed either to open inwards or outwards. They are usually hung folding in solid frames, the openings being frequently used as doorways. In exposed situations there is some difficulty in keeping the weather out, especially when hung to open inwards. A good mode of construction is to form a tongue on the back edges of hanging stiles, fitting into a corresponding groove worked on frame behind the usual rebated stop. The meeting stiles may be finished with a splayed double hook-point or rebate, beaded on the edge, or with a hollow on one edge, and a corresponding projection on the other, locking into each other in the act of shutting. With the first, as a further precaution, a weather fillet may be fixed to lap over the joint on the outside. When a fanlight is required the bottom rail of light and the top rail of sash may be finished with a rebate, or with a hook-joint. When a solid transom is used it should be weathered and throated so

as to throw off the water readily. A weather-board is also requisite along the head of frame for the same purpose. The sill of frame is generally of oak or pitch-pine, sunk, weathered on top, and sunk or tongued to countersill, and rebated inside, with a channel formed to prevent the passage of water. A metal water-bar is frequently introduced—projecting above the sill—of a rectangular or curved form; or a flat bar, hinged, and falling flat when the casement is opened, offers less obstruction. The bottom rail of casement is rebated to correspond with a projecting apron, weathered and throated to form a drip outside. For casements opening outwards the ordinary stop, supplemented by strips of some elastic material, will be found to keep the wet out. The accompanying sketch shows a good method of finishing the sill when no special water bar is used. The channel formed inside the rebate, with the groove over, intercepts any water passing inside. It is conveyed to the outside by holes formed at intervals, as shown by dotted lines. —C. W.

FRESCO.

This art is of great antiquity, and we refer the reader to Mr. Merrifield's and other works on the "History of the Art of Fresco Painting." Fresco is a term only correctly applied to painting upon fresh floated mortar, with water colour in raw pigments, and must not be confounded with painting in oil upon walls—a practice very doubtful, and certainly not durable. The lime and its salts produce rapid decomposition, and turn the colour black, as may be seen in Hampton Court, British Museum, &c. It has been well observed that oil painting is not suitable to a severe style of architecture—it is too rich and varied. In fresco painting the design must be prepared and defined before commencing, as it is impossible to retouch a fresco painting after the mortar has set. The drawings are usually executed with charcoal on paper, and a coloured sketch of the composition should be prepared, as it is difficult to alter colours. Brick-built walls, well dried, and of equal absorbency, are

desirable, but we should recommend hollow walls as the best. In Italy the practice of lathing walls is unknown, though some of the ceiling frescoes are on lath. Lathed walls are liable to bulge. The Munich frescoes are painted on plastered brick walls. In Italy 2 parts of sand to 1 of lime is adopted. The first coat should be rough; and in Munich an admixture of small flint pebbles is used in the rough cast. The selection of lime is important; that obtained from the limestone procurable on Durham Down, near Bristol, has been recommended, consisting of 99.5 per cent. of carbonate of lime, but upon this and other practical points we refer the reader to Mr. Cave Thomas's work on "Mural Decoration."

"Haydon," on fresco, says:—"The power of light which the reflection of lime produces, shining through the colours placed on it, renders fresco, in spite of its deficiency of shadow, fitter for public decoration than oil, whose power lies in its gorgeous shadow. Fresco is not desirable, because it is practised on a despotic material, and therefore requires a resolute and unerring hand, a fixed eye, and steady brain. It is desirable for its beauties, not for its obstructions. You must take the process as it is, and as it has been done effectually by Italians and Greeks, as it has been effectually used as an engine by the modern Germans, though far from the perfection of Raffaele, there is no reason on earth why it may not be also adopted by the British school. Again, as colours are in reality tinted water, and as fresco and stucco have a tendency to imbibe water, colours ground in water become incorporated with lime, water, and sand, and when dry they are not to be again dissolved by water; and the basis of fresco and its colours thus become harder than the stone by drying. If the stucco dry too rapidly, as it always does in a hot climate, it does not dry thorough, and this is the reason why, in my opinion, the climate of England, being moist, is more adapted for fresco than Italy itself. Here certainly we have no chance of fresco drying too soon on the surface; but mortar dries here as hard as in Italy, and wherever mortar dries hard there fresco may be safely practised."—C. P. E.

"J. A." sends the following notes: The walls of the baths of Titus at Rome are covered first with a layer of coarse sand and lime, about $\frac{1}{2}$ in. thick; above this a thick layer of lime and pozzolana, with an admixture of sand and pounded brick; the third and upper coat is of lime and pounded marble. The third loggia of the Vatican, painted by Giovanni da Udine, is much the same as this. The selection of the limestone to be employed in fresco painting, both for the ground and for the white, is a matter of great importance; it should be nearly pure carbonate of lime. Modern fresco painters recommend the lime to be kept a much longer period than Cemmi and other early writers direct. If it is used too fresh it blisters, and sometimes turns the colours to a brownish-red. The lime for the "intonaco" (fresh coat) in fresco painting must not be entirely carbonated or it would not set. The picture must be executed while the "intonaco" is wet or soft, no more work being commenced than can be completed within the time (a few hours) that the plaster takes to harden. Before laying on the "intonaco" the prepared ground must be repeatedly wetted until it will absorb no more; then a thin layer or coat of moderately rough plaster of sand and lime must be laid over as much of the wet surface as can be painted in one day. As soon as this coat begins to set (in about ten minutes or so) another thin coat must be laid on with a wooden trowel, both layers together being scarcely $\frac{1}{2}$ in. thick. Upon this coat the fresco is painted. This intonaco will be fit to paint on in about a quarter of an hour. First process in executing the picture is to pounce or trace the outline of the allotted work, then the painting may be commenced in thin watery washes from the finished coloured sketch. After the first wash is finished, 20 or 30 minutes should elapse for the absorption of the water. While the intonaco is wet, a repetition of the same tint will have the effect of a darker tint—as in tempera drawing. The surface must be kept moist (but not wet) while painting, or the superadded colour will not

unite with the one beneath. When the portion of the picture allotted for the day's work is completed, the superfluous portions of the intonaco should carefully be cut away. In the next day's work the surface must be wetted as before, and the edging of the finished piece carefully moistened with a brush; the operations are then continued as on the previous day. The colours used in fresco painting are all ground and mixed in water, boiled or distilled; they are chiefly earths. Lime, ochres, Sienna, vitriol, Verona green, cobalt, chromo, ultramarine, and vermilion are the chief colouring substances used. Before being applied they must be mixed with white—that is, with lime—which may be considered the vehicle or means of attaching them to the ground. The brushes and pencils are made of hog's hair and otter's hair. Sufficient of each tint is kept ready for the whole picture. The method of fresco secco or dry fresco is thus practised: The plastering of the wall having been completed the whole is allowed to dry. Previous to painting the surface of the intonaco is rubbed with pumice-stone, and on the evening of the day before the painting is to be commenced it is thoroughly washed with water mixed with a little lime; it is wetted again the next morning, and is then ready for pouncing the outline and painting; the wall must be kept constantly moist by means of a syringe. Frescoes are sometimes cleaned by dry bread; sometimes water, vinegar, or wine. Fresco painting may be adopted in the decoration of country residences, but in a smoky atmosphere, or when improper building materials are used, they do not long retain their freshness and colour.

FRITHSTOOL.

Literally "seat of peace" is a seat or chair, says Mr. Parker, placed near the altar, intended for those who claimed the privilege of sanctuary, and for the violation of which the severest punishment was decreed. They were generally of stone, and were hollowed out as at Beverley Minster (see Parker's dictionary), and placed in the north aisle of chancel.

A new hotel is about to be built on the Viaduct and West Walls, Carlisle, from the designs of Mr. Birkett.

Mr. Alderman Thomas Roe, sen., of Derby, the head of the firm of Roe and Sen, timber merchants, of that town, died on Tuesday week, aged 74. Mr. Roe commenced as a wood-sawyer, and some fifty years ago started in business as a dealer in timber, and by shrewdness, industry, and indomitable perseverance developed an extensive trade. Since 1856 he has been one of the foremost members of the Derby Town Council, and lived to see many of his schemes for public improvement (especially those for street widening) carried to successful completion. Amongst these may be mentioned the baths and wash-houses, cattle market, corn exchange, market-hall (the memorial stone of which he laid in 1865 during his second year of office as mayor), widening of Irongate, St. James-street improvement, Sadlergate-bridge, and Siddals-road improvement, and the new thoroughfare from the Post-office to Cheapside, now being carried out by Mr. Woodiwise, the contractor.

Mr. J. Buchanan has been elected draughtsman in the office of the borough surveyor of Plymouth.

New Board Schools have just been completed at Llangedock, South Wales. Mr. John Rees was the contractor.

New schools and residence are about to be commenced at Waldersea for the Wisbech School Board, from designs supplied by their architects, Messrs. Adams and Sen, of Wisbech and Lynn.

A Local Government Board inquiry was held at Merthyr, on Friday, before Mr. Arnold Taylor, in respect to an application from the Merthyr Local Board of Health for permission to borrow £12,120 for the purposes of acquiring additional land for the disposal of sewage, the erection of a new bridge at Troedyrhiw, and for street improvements. There was no opposition to the application.

New Board Schools were opened at Falmouth on Monday. They are situated near Frisey-terrace, and accommodate 300 children. They are Gothic in style, and the plan is that of a Latin cross. The facings are of limestone with Bath dressings and local stone backing; the roofs are open and slated. Attached to the building is a tower with spire of Bath stone rising 80ft. from the ground. In the tower is a clock with 4 dials and bell. Mr. Hicks was the architect, and Messrs. Oliver and Sons were the contractors; the cost was £2,400.

Building Intelligence.

ARMAGH.—A new Presbyterian church in Armagh is approaching completion from the designs of Messrs. Young and Mackenzie, of Donegall-square, Belfast, the contractors being Messrs. James and Jacob Guiler, of Belfast. The church consists of nave, aisles, and lofty tower and spire at the north-west angle of the building. The edifice is built of Armagh marble, but the dressings are of Dungannon stone. The style is Decorated Gothic. The carving has been executed by Mr. Harry Hems, of Exeter. Mr. Rhind is the clerk of the works.

FAILSWORTH.—Dob-lane Chapel, Failsworth, was opened on Jan. 22. The building is Gothic, of the Early Geometric Pointed style. The principal front faces Oldham-road, which is south. The walls are filled with arcading, the panels to be decorated in diaper and stencil work. The seating is pitch-pine, open, with carved bench-ends. The building is heated by hot water. The works have been ably carried out by Mr. David Adams, of Harpurhey, from the designs and under the superintendence of Messrs. Adams and Son, architects, King's Lynn.

ST. TEATH, CORNWALL.—The parish church of St. Teath—perhaps one of the most dilapidated in all Cornwall—is, says a Plymouth paper, about to undergo a thorough and “conservative” restoration. The main fabric was built in the 15th century, but there are earlier remains, and the present tower was added some 200 years later, at which period the interior of the church was remodelled, as is shown by the Jacobean wood-carving in the pulpit, screens, &c., and in the wall decoration found under the present thick coat of white lime. The nave and aisles contain a large number of the original oak seats with richly-carved ends, and on these ancient benches have been erected deal “pens” of various shapes and sizes. All the ancient seats and the interesting Jacobean pulpit will be retained and repaired. Attached to the westernmost benches is an ancient poor-box, probably unique in its decorations. Painted on the several sides are figures representing the maimed, the halt, and the blind. The windows at St. Teath's were formerly filled with stained glass, and fragments, which are to be carefully preserved, remain in the tracery. The nave arcades are each more than a foot out of the perpendicular. The roofs for the most part are plastered over, and the whole interior—walls, roofs, granite columns, arches, and even a recumbent figure of an ecclesiastic—is covered with whitewash. The removal of the nave ceiling has disclosed an open roof with moulded and carved timbers in a fair state of preservation. These will be restored in oak, the arcades will be set upright, the walls and windows put in a substantial condition, and the chancel will be refitted, and a new roof put over it in place of a decayed wooden one. For the greater part of this restoration a contract has been entered into by Mr. Wiffin, of Bradford, North Devon, who will work under the supervision and from the designs of Mr. Hine, of Plymouth.

On Wednesday week the new Church of St. Bartholomew, at Charlton, by Dover, was opened. The building has been in course of erection for the past eighteen months, the architect employed being Mr. F. S. Clark, F.S.A., and the builder Mr. W. J. Adcock, of Dover. The church will seat 750 persons.

The cathedral yard of St. Asaph is being thoroughly and deeply drained in connection with the new system of drainage for the city and district. Mr. Jeffries is the contractor for these works, and also for the sewerage of Denbigh, recently carried out.

A Local Government Board inquiry was held at Taunton on Wednesday week, before Mr. Arnold Taylor, in reference to an application from the town council for sanction to borrow £1,200 for draining the districts of Rowbarton and Sterford. The inspector pronounced the plans satisfactory, except in one matter of detail, and strongly urged the ventilation of all the sewers in the town—a course to which the town council has hitherto been opposed.

The death is announced, at the age of 69 years, of Mr. Charles Christopher Black, M.A., late of the Art Museum, South Kensington.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the ENGLISH MECHANIC AND WORLD OF SCIENCE, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and recipes embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post-free 2d. Office: 31, Tavistock-street, Covent-Garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASSEMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach this office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 60s. 40s. gold). To France or Belgium, £1 6s. 6d. (or 33l. 30s.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted, some difficulty is very likely to arise in obtaining this amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

E. B. B. (You can find the true north by a mariner's compass if you allow for the variation, which is always given for several years in the *Nautical Almanac*. The variation is caused by the shifting of the magnetic pole. Previous to 1657 the needle pointed east of north; in that year it pointed due north in London, and having reached its greatest western variation, some 25°, it is now slowly returning to the north pole, on reaching which it will proceed eastwards, and again return, the period being some 650 years.)—YOUNG CARVER. (Write B. T. Batsford, 52, High Holborn.)—HOPKINS. (E. and F. N. Spon, 48, Charing-cross.)—CHIPS. (We have heard nothing of the Norwegian houses for some time. We believe they were introduced into this country commercially, but don't know. For the purposes you mention we should think Lacelles' concrete slabs would be suitable. You can obtain all particulars from the patentee, 121, Bushill-row, E.C.)—GEORGE LEOE and SON. (We do not give names and addresses.)—H. R. (The most reliable rules are those published by the Local Government Board on work-houses. We do not know of any treatises on the subject.)—H. J. PEARSON. (There are so many books on cottage architecture that it is difficult to recommend. Messrs. Audsley's "Villa and Cottage Designs" is one of the best we know of. There is also a treatise in Lockwood's series.)—RUSSELLS. (Fairbairn's work "On the Application of Cast and Wrought Iron to Building Purposes" is one of the best treatises. On the valuation of property consult a treatise on "House Property," by E. L. Tarbuck.)

"BUILDING NEWS" DESIGNING CLUB.

CONVENS. (We cannot account for omitting to notice in our criticism your drawings under above motto, as it is our rule to mention every design we receive, and we are inclined to think it must have been misprinted under a wrong motto. We shall take care your next design is noticed.)

Correspondence.

"PUT YOURSELF IN HIS PLACE."

To the Editor of the BUILDING NEWS.

SIR,—If I were a builder of some little cunning and no great honesty I might perhaps have some such thoughts as these:—

"My interest is to have bills of quantities 'full.' We all understand, in our trade, what that means. The only point is how to manage it without the knowledge of the architect and the client. To do that we must get the quantities taken out by a builder's man, who is obliged to keep in favour with builders if he means to make a living. Somebody said in the BUILDING NEWS last week that a surveyor is a

builder's man. It was very silly of him to let it out, but it is true, nevertheless. So surveyors' quantities for ever—and down with the architects! Who wants an architect to know where all the 'fat' in a contract is? He will only cut it out, or use it as a set-off against extras. No builder of any sort likes architects' quantities. They are taken too close, for the architect is thinking all the while how to keep the tenders from exceeding his estimate. Some people say, 'Base the contract on the quantities, and then you will be accurately paid for all the work you do.' Now I don't want it to be generally known, but being accurately paid is the very thing I object to.

"How green some people are! It is not very likely I should write to the papers and object to architects' quantities if they were generally excessive. Anybody, you would think, might see with half an eye which system is worst for the client by seeing which is the favourite with one. But let me only send a clever letter to the BUILDING NEWS, and you will find it is not so. Let me throw plenty of mud at architects (anybody is an architect that draws a plan), and I warrant some will stick.

"A first-rate dodge that was that my friend 'Plausible,' the eminent saint and contractor, invented not long ago. 'Plausible' is a great man with the Little Bethelites, and some of them were going to build a chapel. The moment the design was accepted 'Plausible' offered to get the quantities taken out by his own surveyor, and to send in a tender, and further if this tender should be too high, he offered the committee the use of the quantities at a nominal cost to get other tenders from. It was a noble offer, the committee thought, and of course they jumped at it. What 'Plausible' said to his surveyor I don't know, because I was not there. Perhaps he told him to take off the quantities closely and accurately—perhaps he did not. At any rate, by some chance or other they were not so close as they might have been, and I should not wonder if 'Plausible' knew it. He sent his tender in, and it was too high. The committee fell back on his offer, had his quantities copied, and got in other tenders. Far be it from me to lay the fault on the quantities, but the lowest tender was still too high, and the committee were in despair. The difference, indeed, was not above 15 per cent., and the architect could have arranged the necessary deductions in an hour with the builder whose tender was lowest. This builder, however, had no friends on the committee—Mr. 'Plausible' had. His friends went straight off to him and begged him to help them out of their trouble. No doubt he was surprised to see them at the door—no doubt he was grieved to take the work away from the man whose tender had fairly earned it, but in the end his feelings of friendship were too strong for him. He sent the deputation away overwhelmed with gratitude, and bearing with them as a precious document the following:—"Contract: I, Simon Plausible, undertake that the chapel at Goose-common shall not cost more than two thousand pounds, provided I may alter and omit whatever I choose in the plans and specification." On this basis the work was done. There was no searching and spying to see what Mr. 'Plausible' was pleased to omit and alter, for that gentleman's delicate sense of honour revolted against any supervision by an architect. It is believed that the contract was a paying one, and don't I wish I had half a dozen like it? No drawings to be bound down to, no specification to fix the quality of the work, no architect to be always prowling about and finding fault with the materials; and with all this, the quantities well on the right side to begin with. Surveyors for ever, and let every builder get his own quantities taken out if he can!"

Something of this sort, Sir, is what I might possibly think if I were a dishonest builder, waiting for the chance of robbing every one who trusted me. An honest builder (and I believe there are as many honest men in the building profession as in any other) is satisfied with a fair price on a fair bill of quantities, and hence, when the contract is based on the quantities, so that he neither loses when they are "short," nor gains when they are "full," it is a matter of perfect indifference to him whether the architect or any one else prepares them.—I am, &c.,

VERAX.

CONTRACT SCHEDULE OF PRICES.

SIR.—In reply to "Constant Reader" and as one who has had to deal with questions of extras and omissions on contracts extending over many years, I beg to inform him that in ordinary cases the schedule would be applicable to both extras and omissions alike; but cases frequently occur where the extras involve greater expense than the value of a similar quantity of omitted work—for instance, in the case referred to by your correspondent the quality of the material in the concrete may have been different, or the expense of placing it in position greater.

There is another point which architects and engineers frequently lose sight of when they vary the quantity or quality of work in a contract—viz., the builder in most cases, before he sends in his tender, obtains a price and enters into an agreement (conditional on obtaining the contract) for the supply of his materials, and any variation afterwards will be used by the merchant to his own advantage. I have frequently known cases where a builder has bought the contents of a brickfield at a moderate price which enabled him to tender low and so obtain a certain contract. Afterwards the quantity of brickwork was greatly increased, and the builder had to pay 25 or more per cent. for his bricks; on the other hand, the engineer may change his mind after the contract is entered into—not an uncommon thing, I can assure you, in certain Government departments—and availing himself of a schedule of prices substitute concrete for brickwork or masonry. Can he, in all fairness, expect to do this without compensating the builder, who cannot get over his agreement with the merchant except at a loss?

When extras and omissions enter into a contract great delicacy and tact are required so that the builder shall not be a loser nor the employer be charged more than he has a right to pay. These are the cases where an experienced professional surveyor, who is well acquainted with builders and their accounts, becomes of value to an employer, for no one else can protect him from undue claims made by a dishonest builder.

No architect, engineer, or clerk of works can have the experience necessary in cases of this kind, because the builder's accounts and transactions are dead secrets to them, whereas the professional and independent surveyor, from having on previous occasions represented builders, is thoroughly experienced in all their ways, and he only has a chance of detecting whether a builder's claim is trumped up or not.—I am, &c., J. S.

COALITION OF SOME ARCHITECTS WITH QUANTITY SURVEYORS AND CONTRACTORS, AND THE RESULTS.

SIR.—I cannot but coincide with "Old Builder" in his opinion that your correspondent who stated clients must be "green indeed" if they do not know they are charged with bills of quantities, &c., is labouring under a very erroneous impression. If they were aware of it is likely they would, without investigation and remonstrance, complacently pay the surcharges I have drawn attention to, such as 2 per cent., or its equivalent, for bills, 2 per cent. more for measuring and making out the measured-works accounts, 2 per cent. more for making out the day-work accounts, 1 per cent. more for "omissions" (all quantity surveyor's "perqs."), and lastly, 1 per cent. for contractors as contingencies, the whole representing an augmented expenditure over and above the computed cost of the work?

I had nearly forgotten to mention, in connection with these cases, that in the adjustment of the final accounts a large amount of unmeasured work (£50,000 or £60,000 in value perhaps) was settled amicably by the novel expedient of a compromise, which strange proceeding was effected between architect, surveyor, and contractors, at a cost doubtlessly on the broad-shouldered clients for commission to surveyor (in addition to above), say about £1,000, blended and incorporated with the sum fixed upon by mutual consent of the self-elected delegates named.

It has occurred to me, since reading the various contributions on the absorbing topic of

architects and surveyors, and the harmony and concord of contractors—whose lyres are tuned with theirs to one set chord—that I ought to lift the veil that has hazed my letters, and for the enlightenment of the authors of them, to state, in the cases to which I have made reference (which must be, from their incongruity and inconsistency, of a very exceptional character, I would fain believe), the architect alluded to for many years has given his exclusive services to his employers at a remuneration in shape of an annual stipend, of not less than £2,000, but I feel it is due to him to explain that he had nothing to do with the bills of quantities, as those were supplied by a surveyor of something like thirty years' standing; therefore, to put them in the category of "quacks" would mortally wound their highly-sensitive natures. Of the contractors I may say they are men moving in the first rank about town as builders and traders, and the victims or sufferers, *ergo* clients, are corporate and municipal bodies. The locale of the plot is London, within the prescribed limits of the eight-mile radius, and the periods between 1873 and 1878!

It is very curious to note the opinion of those who should be authorities in the matter of percentages, differing as they do so materially, and not the less so respecting the real position of the surveyor. Some aver he is ostensibly the builder's ally, others assert by implication, and some positively insist that he properly belongs to the architect, and that "seldom the contractor has a voice in his appointment." In the cases I have dwelt upon, as I have before intimated, he was employed by the architect (as his note by me will verify), and if not by the builders as well the latter paid him as provided for through their accounts by the delicate process of manipulation referred to, and the trusting, confiding, innocent clients bore the incubus; but "where ignorance is bliss 'tis folly to be wise!"—I am, &c.,

CONSTANT READER.

PENMAENMAWR OR BLUE WELSH STONE.

SIR.—The thanks of municipal engineers and surveyors are due to the Bradford borough surveyor for the letter you kindly published on the 17th inst. Having had some experience of the blue Welsh sett (the principal streets of this city being paved with that material), I can agree with the opinions expressed by Mr. Allison thereon; but if I read a portion of his report aright, I must dissent from what appears to be the wholesale condemnation of Penmaenmawr stone, and as his remarks may have a tendency to mislead those who have not yet had an opportunity of becoming acquainted with the stone now sent from Penmaenmawr, I beg to say that on an official visit to the North Wales quarries last year I found that the proprietors of the blue Welsh stone had ceased working their quarry, and that the other quarries in the neighbourhood were turning out a much superior pavé sett, grey in colour, very durable, and fairly open-grained.

I may also mention that in the construction of the Chester tramways the Penmaenmawr stone, known here as "Darbishires' Granite," is used for paving, in conjunction with setts from other quarries, so that a fair comparison may be made by any one interested visiting our ancient city.—I am, &c.,

J. MATTHEWS JONES, A.I.C.E., City Surveyor.
Chester, Jan. 24, 1879.

P.S.—I see on reading yours of to-day that Darbishires and Co. have written you on the subject, but as they are quarry-owners, an independent testimony may be of more interest to borough surveyors and your readers generally.

At Great Harwood, near Preston, on Wednesday week, Mr. J. Thornhill Harrison, C.E., held a Local Government Board inquiry with regard to an application from the local board of that district for sanction to borrow £1,000 for erecting new offices, a fire-brigade station, &c., in accordance with plans and designs prepared by Mr. J. P. S. Varley, architect. There was no opposition.

On Thursday in last week Col. Ponsouby Cox, one of the inspectors of the Local Government Board, held an inquiry at Lytham, Lancashire, respecting an application for sanction to borrow £6,000 for sewerage purposes, to be expended in the town. There was no opposition offered to the scheme.

Works of water supply are being carried out at Llanelly for the local board. Messrs. Beardmore and Barnes are the engineers, and Messrs. Smith and Fawcels the contractors.

The new Jewin Welsh Calvinistic Methodist chapel, in Bridgewater gardens, Aldersgate-street, E.C., was opened a fortnight since. It represents the oldest Welsh chapel in London, and has been built at a cost of £5,000; 630 sittings are provided.

Intercommunication.

QUESTIONS.

[5660.]—**Sea-washed Road.**—I have built a concrete sea-wall, and have to make a road in front of it 150ft. for public use. There is black clay for basis. The sea rises against the sea-wall about 3ft., so that it is not easy to see how to make a firm road at the least expense. There are no stones within miles, but abundance of clean pit gravel and coarse sand on the spot. Concrete blocks would be too costly. The road will have to be 10ft. wide, and formed with an average of 6ft. depth. Will any engineer kindly suggest the quickest and cheapest way in which I can form this road during tide intervals when the sea retreats from 60ft. to 100ft.? Occasionally the sea is driven 8ft. higher against the sea-wall. I am anxious to make the road as soon as possible to spare public inconvenience.—A SUBSCRIBER.

[5661.]—**All Saints' Church, Stoke Newington.**—Will Messrs. Dollman and Allen, when they supply the particulars of their design of All Saints', Stoke Newington, also explain the scio-graphy of their drawing, which, as you say, has had the double honour of an exhibit in the Royal Academy, and also in your pages? How do they account for the miraculous tower shadow on the main roof, and for the absence of shadow on the north gable of west porch?—AN ARCHITECT.

[5662.]—**Builders' Charges.**—Some months ago a builder in one of the midland counties was asked by an architect to tender for alterations proposed to be made on a certain building. As no plans had been prepared he was instructed to visit the building himself and take all his own particulars. He did so, but as his tender was thought to be high another contractor was called in, and his tender being much lower was accepted. The first named builder now sends in a bill to the architect for time spent by him in visiting the building, and also charges for quantities—viz., 1½ per cent. on the amount of his tender. Perhaps some of your numerous readers will kindly inform me whether it is customary for builders to charge architects for time spent in preparing their tenders, and if such a charge would hold good in a court of law.—GREENHOOD.

[5663.]—**Plain Tile Roofs.**—Having noticed that wet was penetrating in many places the roof of some houses I have under my care I had the roofs repaired, but found that they were worse after the operation than they were before. I had them again repaired, and the result is worse than ever. They are covered with plain tiles, and to outward appearance seem to be sound and in good condition. They are, however, old, and it has occurred to me that the mere fact of workmen getting on them may probably be the cause of fresh drainage. Doubtless others have met with similar cases, and I should be greatly obliged to any one who will be kind enough to give me the benefit of their experience in such matters, and help me to finding an effectual remedy.—W.

[5664.]—**Sea Water.**—Will some one kindly inform me how and in what way sea water mixed with lime would affect it chemically, and if the same effect would be produced on Portland cement as on ordinary grey-stone lime or lias lime, also for what reason is sea sand objected to for mortar and cement work generally?—J. X. B.

[5665.]—**Strains.**—Will some reader kindly show how the strains in roof trusses are measured (as for example in a kingpost roof-truss) by graphical means, and how to calculate weight borne by each point of support of truss? A diagram showing strains worked out would greatly oblige.—MUDDLED.

[5666.]—**Carrying Weight of Bridges.**—Is there any simple rule for calculating approximately the weights brick or stone bridges can carry?—C. S.

[5667.]—**Portland Cement.**—Can any of your readers furnish information as to the first inventors or introducers of Portland cement? I find in the new edition of "Encyclopædia Britannica" that Mr. Parker was the first introducer of Roman cement, made from the calcareous nodules from the London clay and other similar formations. Also that General Pasley in England and M. Vicat in France made experiments in the formation of an artificial hydraulic cement, but the authors of the system of making cement from river mud, clay, and chalk—Portland cement, in fact—are merely referred to as the "inventors." Who they or he were, and some notice of the early history of what is now so familiar, would greatly oblige.—CRETA.

[5668.]—**All Hallows, Bread-street.**—May I ask, through the medium of your paper, if it be intended to incorporate, in the buildings now being erected on the site of the above church, the tablet commemorative of Milton, so well known to all passers-by in former times?—COMUS.

REPLIES.

[5641.]—**Flues.**—I beg to support the idea that the present large area of our chimney flues is an absurdity. Instead of 9in. by 14in., or even 9in. by 9in., I consider a 6in. pipe would be ample for rooms, and also kitchens of smaller houses, while a 7½in. pipe would do for larger kitchens, where extra large

fires are kept on. The area of my own kitchen vent was 12in. by 12in. I put a chimney can upon its top, 6in. diameter at the bottom, and it works quite well.—W. P. BUCHAN.

[5645].—**Stability of Walls.**—The rule for the resistance when the face of wall is at right angles to the surface of ground at top is given by Prouy, and is $R = \frac{w}{2} h^2 \tan^2 \frac{1}{2} c$, in which R = horizontal resistance, w the weight of a cubic foot of bank, and h the height of wall, and c the angle made between fan of wall and line of repose of the material. For about one-third the height of such a wall the thickness should be about one-third of the wall's height. When the top of bank slopes at the angle of repose, the resistance required is about double, or not greater than 3 to 1. In reservoirs the resistances are equal.—G. H. G.

[5646].—**Condensation on Walls.**—The painted surfaces might be prepared, but the best plan is to remove the paint and plaster the walls. If ventilators at the ceiling line and inlet opening at the skirting level be introduced, I do not think there would be much condensation. There is a very good lining for walls upon which moisture does not condense. It is made of a species of linoleum, and is called the "Sunbury Wall Decoration."—G. H. G.

[5646].—**Condensation on Walls.**—Instead of reading "that during wet weather," &c., "there appeared," read "that during hot weather," &c., which completely alters the sense.—C. C.

[5647].—**Glass.**—White obscured glass, similar to white gas globes, may be obtained in sheets of all thicknesses. Sheet and plate glass may be rendered white obscured by rubbing flour, emery, and water over the surface with another piece of glass.—JOHN ALGAE.

[5651].—**The Use of Statuary Marble in Outdoor Work.**—Statuary marble is not used with any success in outdoor work in this country. Cemetery masons affect it sometimes, but the material has no stability.—A. M.

[5651].—**The Use of Statuary Marble in Outdoor Work.**—Statuary marble is never used for outdoor work by any one who understands the resisting powers of foreign marbles. There is probably not a statue in Great Britain made of that material standing anywhere out of doors. If such a mistake does exist, it has undoubtedly lost all elegance of detail or sharpness of outline, as the marble has become so "angry" that it is wearing away. I fully confirm Mr. Harry Hems' experiences and think with him that the sharp London marble merchant was merely "trying it on" with the provincial architect.—YORKSHIRE.

[5651].—**The Use of Statuary Marble out of Doors.**—The Exeter architect will eschew the use of statuary marble for exterior work if he be wise. Statuary is a delicate and expensive material, admirably adapted for internal sculpture, but utterly unsuitable for external uses. It is not only unable to resist the influences of our climate, but it is in other respects altogether too delicate a stone to admit of its withstanding the thousand and one dangers to which it would be exposed in such a position. It stains so readily that where Sicilian or similar marbles would go scot free statuary would be irredeemably ruined.—J. T. D.

[5652].—**Cast of Carvings.**—Impressions from stone carvings may be readily taken with ordinary modelling (pipe) clay. Let it be kneaded up to the consistency required for general modelling purposes—i.e., soft but not sticky. This done, it is a simple matter to take what is technically called "a squeeze" of the carvings desired. In pressing the clay on, take care that it gets into all the recesses and shadows, and then lift the whole off in a lump. Place this, inverted, upon a board, and a cast may be obtained at leisure. To do so, mix up plaster of Paris in a bowl, under the ordinary fashion, and then turn it into the clay mould. In ten minutes or so the plaster will have set, and a perfect cast will be the result. Now tear away the clay, carefully pick out any little bits of plaster, &c., that may be adhering thereto, and it is ready again for fresh "squeezing" purposes. Pipeclay is procured in large quantities in Devon, principally in the neighbourhood of Chudleigh. Its cost, in Exeter, is a shilling a quarter of a hundredweight. In London the price is a trifle higher, I think. The Princess Louise, whose taste for and skill in modelling is well known, has recently found to her concern that no modelling clay was to be found in Canada. A quantity of it has just been sent over from this country for her Royal Highness's especial use. Pipeclay, however, is much too dirty a material for using upon woodwork. It answers the purpose, but it leaves a stain that comes out some twelve hours after it has been pressed upon the carving. This blot is an exceedingly offensive white patchy mark, which adheres so tenaciously to the place that nothing but endless scrubbing will eradicate it. The best thing for using on woodwork is "squeezing" wax. It is applied precisely as the clay is used. Squeezing wax cannot—so far as I know—be bought. I gave a receipt for making it in these columns four years ago to-day (BUILDING NEWS, Jan. 29, 1875). The cost of ingredients for making it is about 2s. 6d. per lb. Like the clay, the same wax may, with ordinary care, be re-used over and over again—for a lifetime, in fact.—HARRY HEMS.

[5655].—**Surveyors.**—In reply to "Surveyor," the practice has always been where the employer and the builder each nominate a surveyor, that they do the work between them—the builder's surveyor taking the lead as representing the party whose interest is most vital, while the employer's surveyor does the checking, each surveyor writing his own dimensions, which are afterwards squared, and then compared with those of the opposite party; but as there can only be one abstract, it should be prepared by the builder's surveyor, and checked by the employer's. From this abstract, when completed and checked, the bills are made out by the builder's surveyor and checked by the other. Both surveyors are then legally responsible to their employers for errors, but when the architect takes the matter into his own hands, he or his surveyor only is responsible to the employer, and it is open to the builder to question the accuracy of the account. When the surveyors are properly nominated by each party, they act somewhat as arbitrators, and the arrangement comes to be binding on both parties, each, however, having a remedy against his own surveyor in case of fraud or collusion.—J. S.

[5655].—**Surveyors.**—In reply to question (a), the proprietor's surveyor is bound to watch his client's interests, and to render every facility to the builder's surveyor; the builder's surveyor acts also for his employer's interests, and has perfect liberty to interpret the quantities his own way; of course, with a due regard to the explanations of the former.—G. H. G.

[5656].—**Esthetics.**—I cannot now furnish a complete list, but the most important English works on Esthetics are "Burke on the Sublime and Beautiful," "Alison on Taste," Hogarth's "Analysis of Beauty," a treatise in the Encyc. Brit., Ferguson's "Enquiry into the Principles of Beauty in Architecture," Garbett's "Treatise on Design," the Earl of Aberdeen's "Inquiry into Principles of Beauty in Grecian Architecture." I may mention a few very important philosophical works on the same subject, in which esthetics is rescued from mere sentiment and explained upon physiological principles. The chief of these are by Herbert Spencer in his "Miscellaneous Essays," by Professor Bain on the "Intellect and Emotion," a treatise by Grant Allen, and only lately an interesting work by Eugene Véron, a translation of which has just appeared. Shall be pleased to furnish any particulars on the above works.—G. H. G.

[5657].—**Slaughter Houses.**—I beg to refer "J. J." to the article on "Abattoirs" in the "Commonplace Column, where information can be obtained.—A SUBSCRIBER.

[5657].—**Slaughter Houses.**—In order to render them perfectly wholesome, they should be floored with asphalt, and not with brick, stone, or other absorbent material. Claridge's patent asphalt is perfectly impervious and inodorous, but many descriptions of the so-called "asphaltes" are not so, these latter containing gas tar as an ingredient, which imparts an offensive odour to the meat. Claridge's asphalt when laid represents in appearance and effect a slate over the entire area of the floor, and it contains no open joint or inequality of surface to admit of the lodgment of offensive matter. A moderate supply of water is all that is necessary to flush the floor, which readily dries. Squeegees, now so generally used, are well adapted to cleanse floors of asphalt. Claridge's Patent Asphalt Company recommend, in order to secure perfect cleanliness, that the walls of all slaughter houses should be asphalted to a height of, say, 3 or 4 ft. above floor level.—ONE WHO HAS TRIED IT.

The Free Library Committee of the Derby Town Council have accepted the tender of Messrs. Best and Lee, of Manchester, for the decoration of the free library and museum now in course of completion from Mr. E. K. Freeman's designs. The painters of Derby held a meeting on Tuesday week to protest against the "work being given," as the placards announced, "to a firm away from the town without submitting the same to fair competition, while a great number of the painters of the town are out of employment." A motion expressing disapproval of the action of the town council was passed.

The Metropolitan Board of Works decided on Friday to make additions and alterations to the freehold building occupied by the brigade in Southwark-street, to enable it to accommodate not only the men attached to the B float, but also some of the additional men to be stationed at night in the City. The cost of the works is estimated at £1,400.

The Camborne Local Board received on Friday evening a number of tenders from contractors in Cornwall, Devon, and Somerset, for the construction of a system of sewerage for the town. The lowest, that of Mr. A. Dalbridge, jun., was accepted at £3,302 16s., and Captain Argus, town surveyor, was appointed clerk of works.

Steady progress is being made with the Metropolitan and Harrow Railway extension, from its commencement at Brompton-bury or Edgware-road, through Sheriff-green, Neu-don, and Duddinghill. The line is being carried through the latter by a cutting.

Our Office Table.

ACTIVE steps are being taken by some City people and others to preserve the churches which are proposed to be pulled down in connection with the Inner Circle Railway scheme which is to be brought before Parliament during the ensuing session. A "City Church and Churchyard Protection Society" has been formed, the committee including Lord Houghton, Mr. Beresford Hope, M.P., Sir Walter Barttelot, M.P., and Mr. Geo. Edmund Street; while in active co-operation is the Society for the Protection of Ancient Monuments. It is generally believed that the Corporation are in favour of the railway scheme, which is considered to be a public necessity, so that the efforts of the society are to be directed to that portion of the bill which interferes with City churches, in order to see whether the projected line could not be diverted so as not to destroy them. One of the scheduled churches is St. Mary-at-Hill, Love-lane, East-cheap, the line striking through the centre of the building. The bill will meet with considerable opposition in Parliament.

A NEW institution at Brighton, to be known as the Nineteenth Century Club, which has been founded and started at the expense of Mr. P. Taylor, M.P. for Leicester, virtually as an experiment to test the actual practicability of opening libraries, museums, and other places of national recreation on Sundays, was opened on Monday. The members will have the institution for their exclusive use on week days, having, besides other conveniences, the advantage of a large library of books, the property of the hon member, who lends them to the club on the stipulation that the library shall on Sundays be open in some reasonable manner to non-members as well as members. Women as well as men will have access to the club, which starts with no definite programme as a political institution. The name has been aptly chosen, for in this nineteenth century the will of the people will not much longer tolerate public museums, libraries, and art galleries being closed against them on Sundays.

An interesting paper on the "Architectural Terra Cotta at the Late Paris Exhibition," written by Mr. George Bedford, one of the delegates of the Society of Arts, appears in the *Salopian and West Midland Monthly Journal*. The following extract is interesting, and should be suggestive:—"The Ceramic Union of France was founded in 1870, between makers of terracotta and fire-clay goods, its purpose being to discover and propagate the best methods of manufacture, to consider all industrial and commercial questions which might concern the manufacturer, and to receive and give, upon as large a scale as possible, any information likely to be interesting to its members. To effect these objects it endeavours to enrol foreign manufacturers, to obtain agents and correspondents in foreign countries, to procure the advice of men of science as to the fitness or otherwise of new materials, and generally to discover and consider all that is, or is likely to be, useful in assisting the progress of the industries concerned. The results are made known by means of a journal, which is published every month, and distributed to the members, of whom there are 137, all French, except a few from St. Petersburg and Madrid. We inquired of one of our principal manufacturers how it was that there were no English firms in the society, and the reason given was that we had nothing to learn from other nations in the manufacture of terra cotta. This may be, and probably is, the case, but there is no reason why we should not learn from one another, and we venture to think that if the mutual jealousy of English manufacturers could be overcome and a similar society to the Ceramic Union of France founded in England, many improvements in material and manufacture would probably result."

It often puzzles people to know what becomes of sewage when it is applied to land in a frozen state, and Mr. J. Bailey Denton therefore calls attention to the fact that although we have had about eight weeks of continuous frost, there is no difficulty whatever in filtering sew-

age through natural soil if properly prepared for the purpose, and of securing by that means an effluent admissible into rivers. On Friday last a deputation from the borough of Dewsbury visited the sewage land at Barnsley laid out by Mr. Bailey Denton for intermittent filtration two years back, and witnessed the application of the sewage of that town, of about 27,000 population, to a comparatively small area of land which had received it alternately with another area of equal extent all the while the frost has lasted without any interruption whatever. The effect of applying sewage intermittently in a concentrated quantity on a small area of land is to keep the land thoroughly open for percolation, the temperature of the sewage being sufficiently high to thaw any ice that may be formed on the surface during the interim when the sewage is not on the land. At Barnsley there is no sub-soil water to dilute the infiltrated sewage. Hence the effluent, which has been declared by both Dr. Tidy and Professor Atfield to be well within any recognised standard of purification and quite admissible into a river, is sewage, and sewage only freed of putrescible matter.

MR. JOHN ALLISON, borough surveyor of Bradford, was on Tuesday appointed by the special committee of the Manchester Town Council to the office of city surveyor of Manchester. The salary is £1,000 a year. There were 49 applicants, and Mr. Allison was chosen out of the selected six. Mr. Allison has been borough surveyor of Bradford since 1874, and his salary was £500 a year. He has given great satisfaction by the discharge of his duties at Bradford, and will doubtless be popular and useful in Manchester.

On Thursday week, in the Hall of the Drapers' Company, the Lady Mayoress distributed the prizes gained in the competitive exhibition of fans, promoted some time since by the Fanmakers' Company, and attended by nearly 12,000 persons. The first prize, which consisted of a gold medal, twenty-five guineas, and the freedom of the company, was awarded to Miss Elizabeth Laird, of Belfast, for the best fan wholly of British manufacture. Mr. Wallace, one of the judges, stated that he had felt it his duty to recommend the purchase of certain fans for the Museum at South Kensington, where they could now be seen.

THE Bishop of Gloucester and Bristol, in his annual address, refers to the progress of church building and restoration in the diocese during the past year. In Gloucester Cathedral, he says, the work has been mainly confined to the thorough restoration of the four beautiful pinnacled turrets that form the chief feature of the nobly proportioned and majestic tower. The cost has been very great; probably each turret, owing to scaffolding and the skilled work that is required, involves a cost of not less than £800. In Bristol Cathedral the dean and chapter have resolved not to proceed with new work until all liability has been cleared away from that already done. The cost of this present completion-work has been £3,610, and

towards this all has been received but £75. When this is cleared off the dean and chapter will make a new public appeal, and solicit aid for proceeding at once with the still great work that remains to be done. A most successful service was held in the new nave last Advent, when fully 3,500 persons were present, and the question of what would be the use of the new nave was fully and finally answered. The amount of general church restoration is, perhaps, somewhat less than in former years; but this arises from the fact that so much has been done that less and less remains every year. The cases that are yet left, however, nearly all involve great outlay, and have been delayed thus long from the magnitude of the work in each case to be accomplished. Reference is made to the reopening during the past year of Chippenham, North Cerney, Charlton, King's Corsham, and Littleton-on-Severn churches, and to the works of restoration in progress at Coleford, St. Peter's, Clifton-wood, and St. Matthew's, Cheltenham. Much of the work is completed at Tewkesbury Abbey, which will be reopened in the summer. Alluding to the recent destruction by fire of the fine Church of St. George's, Gloucestershire, Dr. Ellicott urges the prudence of insuring churches to the entire value, remarking that "to introduce warming arrangements into a church, and not at the same time to insure the church to its full amount, is reckless and culpable."

THE first annual meeting of the National Association of Master Builders of Great Britain was held on the 23rd January, at the Masonic Hall, Leeds, when representatives, numbering upwards of 70, from local associations, were present. The report of the council announced a very general reduction of the rates of wages, and in some cases an increase of working hours in the various branches of the building trade as likely to come into operation at various periods during the coming spring. The meeting also discussed and approved of a form of contract which had been prepared and recommended by the council for general adoption throughout the building trades in the country, the contract being based upon the conditions of contract agreed upon by the Royal Institute of British Architects and the London Builders' Association. The association now embraces the local builders' associations of nearly all the principal towns and cities in the country, and the council are still assisting in organising new associations in towns where none exist, with a view to their amalgamation with the National Association. A strong opinion was expressed at the meeting that the proposed reduction in the cost of labour will lead to a general improvement in trade, and thus benefit both workmen, employers, and the public.

MESSERS. BENNETT AND VALON have made a report upon the electric lighting experiment at Westgate-on-Sea. Six Jablochhoff lamps were tried for four hours every night, and the average illuminating power of each lamp was found to be equal to 197 candles. From a comparison of the total expenditure with that

required for an equivalent illumination from gas, it appears that the electric lamps or Jablochhoff candles cost upwards of £23 more than would have been expended in the equivalent of coal-gas, which at Westgate is both inferior and dear. With London gas the figures would have been £7 18s. 9d. as against £40 9s. 4d. for 96 hours' lighting.

CHIPS.

The voting on the question whether the new convention respecting the St. Gothard Tunnel should be carried out—which had been referred to the Swiss people—has resulted in a very large majority in favour of the convention. This insures the completion of the enterprise.

The Ramsgate Improvement Commissioners have received upwards of two hundred replies to an advertisement for designs for the proposed marine drive to connect the East and West Cliffs.

Constantine Church, situated midway between Penryn and Helston, was reopened last week, after restoration under the care of Mr. J. P. St. Aubyn. The most important feature of the restoration is the substitution of an open roof for an old low-cabled roof. A new east window with painted glass, by Lavers, Barraud, and Westlake, has been put in, and a new reredos erected. The cost incurred has been estimated at £1,200.

At a meeting of the governors of the Harpur Charity Mr. Henry Young was appointed surveyor to the estate in Bedford. There were three other local candidates.

The Maidenhead Town Council last week accepted the tender of Mr. Kingler (the lowest received) for the execution of improvements to the town hall.

Mr. Belt, whose design for the Byron Statue was selected by the committee at the open competition in June, 1877, has now completed the clay model, and will shortly proceed to take the plaster cast of the statue.

At a meeting of the Bricklayers' Association, held at Otago, November 19, 1878, it was decided to increase the rate of wages from 14s. to 15s. a day. At a meeting of the City Council, which took place on the same date, it was stated that "it was impossible to get a bricklayer for a day or two's job for less than £1 a day."

A public meeting was held at Epsom on Wednesday week, at which it was decided to take steps to build a town hall, with a room for 600 people, and that, if possible, it be built on the open space in the centre of the High-street, steps to be taken to provide a public market. In order to raise the requisite funds a limited liability company is to be formed of 6,000 shares at £1 per share.

The tender of Mr. Alfred Robinson has been accepted by the Dean and Chapter of Salisbury for the screen of woodwork to be erected in the north transept of Salisbury Cathedral for the purpose of enclosing the apparatus for blowing the organ. The designs were prepared by Mr. G. E. Street, the architect to the cathedral. During last week workmen were employed in removing the hoarding which has long separated the nave from the north transept.

The South Kensington Council on Education have accorded a full certificate for freehand drawing, practical geometry, linear perspective, and model drawing, to one of the pupils of Mr. H. Musker, head-master of St. Barnabas Schools, North London. The boy in question, Francis James Bancroft, is only 14 years old, and great credit is due to the master for this more than ordinary success.

THE BUILDING NEWS.

LONDON, FRIDAY, FEBRUARY 7, 1879.

THE METROPOLITAN FREE HOSPITAL COMPETITION.

SCHELDOM have architects a more difficult task set them than that of providing hospital accommodation in a narrow street plot, hemmed in on two sides by lofty buildings. Such a problem has just been worked out for the Metropolitan Free Hospital Committee, who invited six architects to prepare plans for the new building proposed to be erected on a freehold site in Bishopsgate-street Without, to replace their old premises in Devonshire-square. The architects invited to submit designs were—Mr. Charles Barry, President of the R.I.B.A., whose acceptance must have surprised those who remember some recently-expressed opinions of his on competitions, Mr. Chatfield Clarke, Mr. H. H. Collins, Mr. James Edmeston, Mr. E. P. Owen, and Mr. Ebenezer Saunders; and the committee, in compliance with the advice of the Royal Institute of British Architects, submitted the drawings to Mr. Edward P. Anson, who has acted as assessor, and whose recommendations have been, we believe, unanimously adopted.

The result of Mr. P. Anson's report is that the design with motto "Ad Rem" has been placed first in order of merit, the authors being Mr. H. H. Collins, of Old Broad-street, E.C., and Mr. James Edmeston, of Great Winchester-street, E.C. By a singular coincidence, the second best plan, under motto "Civis," in a red lozenge, has fallen to the same gentlemen—Mr. James Edmeston and Mr. H. H. Collins, who have jointly sent in both designs. The most important conditions imposed upon the competition had reference to the areas for light and air, which made it almost necessary to raise the building to a greater height than necessary or desirable. Half Moon-street, which forms one boundary, is contracted, and necessitated the setting back of this front—a circumstance which some of the competitors have availed themselves of. Another important condition was the requirement of distinct entrances to the out-patients' waiting-rooms, and a separation of this department from the hospital. One of the greatest difficulties in the way of a perfect plan is the great notch in the site made by "Paul Pinder's" house—a relic of Old London it would be almost a pity to sacrifice. Moreover, a limit to the height of building was imposed of 73 feet, and this in some cases has been met by sinking the out-patients' waiting-rooms, and in one case by a wider area. Altogether we may congratulate the committee on having obtained such an ingenious set of plans for a site which offered unusual difficulties.

Looking over the design "Ad Rem," we cannot fail to observe a well-considered, if not clever, plan, in which the authors have certainly made the most of a very difficult and cramped site, and the conditions imposed. The agreement entered into between the Committee and the Great Eastern Railway Company made it necessary to curtail the building area. It compelled certain areas for light and air, and we find the authors have judiciously met these by providing areas on both sides of the wards, partly by setting back the frontage in Half Moon-street. By these means also a greater height of building is possible, as the angle of light as regards the opposite buildings is not encroached upon. We find the basement plan provides for the dispensary in the rear of the site, and is approached by stairs from the side street area. It is lit by a sky-

light and court. The position seems convenient of access from laboratory and the ground-floor. The kitchen, offices, and stores have a long corridor entrance which appears ill lit—at least we do not see provision for lighting it. The ground-floor is economically planned; the waiting-rooms for male and female out-patients are separated by two respective consulting-rooms, have their own entrances, and are lighted from Half Moon-street. A long corridor brings them into communication with front hall and stairs, and this is lighted by skylights. The front is occupied by the surgeons' and porters' rooms. The accident ward is convenient to the surgery lift or staircase. We observe the upper or ward floors have been planned on the pavilion system. On the first floor there is a large female-ward, 98ft. by 23ft., for 24 beds, lighted and ventilated on both sides, and giving 1,500 cubic feet to each bed, these being ranged along the walls between windows. This ward occupies the main rear portion to Half Moon-street, and is well approached by stairs and lift, nurses' room and scullery being at the same end; and we may here remark upon the great importance of having the nurses' rooms near the stairs and lift as an element in facilitating the service. There is one feature in this plan that gives it a decided advantage over others, and that is the isolation of the w.c., lavatory and bath-rooms from the ward. These on each floor project and occupy the area on west side of ward, and are approached from each ward by a lobby or passage, cross-ventilated, so as to shut off all risk of contamination. The front room of this floor is a board-room and Secretary's office. The second floor has two wards, each 38ft. by 23ft., divided by a children's ward and nurses' rooms, and these are appropriated to Jewish patients. The corridor along the side is supported and forms an iron-covered balcony, by which means light and air are obtained below for the female ward, &c. At the Bishopsgate end is a convalescent ward. The third floor has another long ward for 24 beds, and follows the female-ward; the surgeon's sitting-room is in front. The fourth floor is a repetition, while the kitchen and bedrooms and operating-room are on the top floor. The chief points in this plan is the central and convenient position of the stairs, lift, and nurses' rooms, and the detached position of the latrines, making each ward independent, and practically isolating it as much as possible from the administrative portion. Speaking of the kitchen offices, the authors say in their report, "With respect to placing the kitchen offices on the upper floor, it is not recommended, although provided. It will occasion additional service and expense, whilst its advantages are exceedingly doubtful. For example, it will necessitate having a special domestic to receive the goods and to give orders, and will require a double and constant supervision, whilst every article of food will have to be conveyed by means of the lift to the upper floor." Facility of transit in the food is certainly hindered by this roundabout mode; but the question is whether the funes of the culinary operations can be effectually cut off from the wards otherwise. The details of this design are certainly well studied; the windows are "hopper," the top easement falling inwards. Cold air is admitted by flues at the top of the building, so as to get it free from impurities, thence passing over coil pipes into the wards, and we see also air ducts under the ward windows are shown opening into the ward at the sides. Galton's stoves are used besides coils in the window recesses for warming; Verity's exhaust apparatus is proposed to extract the vitiated air; the wards are intended to be finished in silicate enamelled paint, with doweled floors, while Pearson's apparatus without traps, and other sinks and lavatory fittings of Bower's and

Jenning's manufacture are specified. We notice also Pott's Edinboro' traps and Banner's cowl to the said pipes. In design "B" the wards are crosswise with end windows, and the whole of land is utilised, but the planning is less effective. In style, the architects have chosen Italian of a very used-up type toward Bishopsgate-street, contrasting poorly with Sir Paul Pinder's house. The elevation is altogether unworthy of the plan, and we believe the architects will be requested to remodel this portion of their design. The estimate has been worked out at 9d. a foot cube to £18,000. The next design "Civis," in a lozenge, placed second, has undoubted merits, but the authors have disposed their wards (L-shaped) on each side of a central stairs and lift towards the side street. An area is left on both sides. The ground plan has the out-patients' waiting-rooms facing Half Moon-street, with entrances on each side of a centre vestibule, and lift and a porters' room reached by a few steps descent from street level; in front is the administrative department, accident-room, &c., while on the inner side are consulting-rooms, approached by a corridor from the front, in which we find steps, certainly undesirable. The basement contains the nurses' and housekeepers' rooms, cellars, dispensary, and laboratory in communication. On the first floor the wards, as noticed above, are placed on each side of the stairs and lift; the lavatory and w.c.'s occupying a front bayed projection towards the side street, and the nurse has also in this central division a room which commands both wards. There are twelve beds in each ward and separate sets of lavatories to each. The arrangement at the bend of site, between wards and front department, is somewhat confused, and is, perhaps, the least happy part of the plan, though economy of service and good lighting have been kept in view. On the second floor there is a convalescent room, facing Bishopsgate-street, with balconies; and the windows of this elevation, particularly the recessed bays of this and the first floor, are excellent features. The wards are devoted to Jewish patients, ten beds in men's ward, eight in the women's, and six in the children's ward, with small rooms for acute cases. The third and fourth floors have each two general twelve-bedded wards, arranged as on the first floor, kept separate by the intervening stair and lift, nurses' room and lavatories, and a mezzanine floor of two rooms is provided over one set of these conveniences on each floor. The sitting-room and bedroom of the house surgeon, matron's rooms, &c., are placed in front, while the top floor is devoted to servants' rooms, kitchen offices, operating theatre, &c. As in the first plan, the authors show an alternative basement arrangement for the kitchens. We notice, too, that 100 cubic feet of additional space has been given to each patient by this plan, 1,200ft. being the specified minimum. Generally the private entrance and official part have been kept distinct from the hospital proper; the communications are good, and the wards well separated and lighted. The waiting-rooms and their respective conveniences are also distinct and under the porter's eye, and on the whole the authors have closely followed the conditions. The elevation towards Bishopsgate-street is boldly conceived, and in architectural merit must be placed before that of "Ad Rem." The recessed bays in shallow cants of the principal floors, the open loggia entrance, and the pedimented superstructure form a dignified front not wanting in character. The style is Italian. We do not like the unsupported ends of the entablature, which appears to finish unsatisfactorily. The side elevation is spoilt by the number of small windows. The estimate is £18,000.

We may make a few comments on the unselected designs, and of these one under a

Hebrew motto, "I will heal" (Mr. E. Saunders) has some good points in planning. This remark applies, however, more to the upper floors than the ground floor arrangement. The glazed partitions between the waiting-rooms and corridors are objectionable. The entrance from Bishopsgate-street is on one side, leading to an awkwardly shaped hall and staircase, with a long corridor approach. The rear portion of site above is occupied by large wards, 69ft. by 30ft., for 30 beds, a double row being placed down middle of the ward in addition to the side rows. The wards are lighted on both sides in Half Moon-street, and by an open area, but the stairs and landing are awkward, and the w.c.'s are attached. The first floor arrangements show the surgeon's rooms in front, and on the second-floor, the front room is made a convalescent ward. The external treatment is in a poor pseudo-Gothic dress of late character, and the side elevation has a too warehouse look. Another well-studied arrangement, though not faultless, is "Experientia." On the first-floor plan is a long corridor, lighted by area and ceiling lights, the wards placed lengthwise to Half Moon-street, but no cross current is obtained, although we observe in the plans provision for air-ducts in the inside walls. There is one front ward for 9 beds. The position of the doctor's rooms in the rear portion is objectionable, and the closets and lavatories are not arranged upon the best principles. On the other hand, something must be said for the arrangement; there is a studied regard for light, the hall entrances and stairs are spacious. In elevation, the author (we believe Mr. Chatfield Clarke), has given something dignified and suitable in which open fenestration is the main feature.

The author of "Civis" (we believe Mr. Charles Barry), places his male and female out-patients in the rear, divided by a serving dispensary in an economical manner; the surgery, consulting and dressing-rooms are also conveniently planned; but there is a highly congested and crowded look in the centre part between hall and stairs, and the waiting department, the lavatory, w.c., &c., are rather confused, and the wards are not well lighted or ventilated, especially the cross one. The administrative arrangements cannot, on the whole, be pronounced satisfactory for economical working. In external design, a tawdry kind of Italian has been adopted much more fit for the front of a warehouse than a hospital. "Proof," by Mr. E. Parry Owens, shows a sub-ground-floor arrangement; there is a good division of out-patient's entrances and exits, the dispensary is placed in front, with a large waiting lobby. Above, the wards are arranged on both sides, one along Half Moon-street, and the other on the left, rather poorly ventilated. There is a plain, dignified elevation, chiefly in brick, in a species of moderate Queen Anne, facing Bishopsgate-street, but the side front is not happy in its roofs. On the whole, it is one of the best sets of drawings, and the details are carefully considered.

Since we inspected the drawings, we have heard that it is the intention of Mr. E. P. Owens to protest against the award, on the ground that the two competitors whose designs have been placed first and second had no right to combine in the manner they did to send in two designs. We believe Mr. Owens' contention is that the second plan sent in by Messrs. Edmeston and Collins ought to have been submitted as an alternative design under the same motto. We cannot see that the objection is worth much consideration.

At Wincanton police-court, on Monday, a Bruton solicitor was fined 30s. and costs for assaulting Mr. Thomas Pike Davis, architect, of Taunton, when in a hotel at Bruton.

ENGINEERING AND ART.

IF it has been found somewhat difficult to draw a line between engineering and architecture, or to discriminate where the one ends and the other begins, it cannot be surprising that the same difficulty meets us in defining the separation between engineering and art. Mr. Charles H. Driver, F.R.I.B.A., in a paper read by him before the Civil and Mechanical Engineers' Society last week, selected the heading to this article as the subject of a discourse; and as the theme is one of considerable interest to both professions, we may here consider the argument broached by the author. Mr. Driver divided his subject under three heads: 1st.—What is Engineering? 2nd.—What is Art? and 3rd.—Are Engineering and Art of service to each other? and can they be united? It is, of course, absolutely necessary, before discussing such a theme, to define the terms, and the author has done so by designating Engineering as the "science of construction," and "Art as the result of the endeavour of the human mind to achieve the perfection of beauty, whether it be in form, colour, or sound." We cannot quarrel with the definition of engineering, but to that of art we may take an exception, inasmuch as it appears to exclude construction and all idea of utility—in other words, an object for the exercise of art. If the definition had run: "Art is the result of the endeavour of the mind to achieve perfection in form, and colour, and sound by adding a sense of pleasure to that of adaptation," it would have been nearer the truth, for the great error which has overtaken most of the older writers on art is that of making it something quite distinct from use, and therefore something that can be acquired without reference to the useful. The great barrier between engineers and artists—the hiatus, or want of art Mr. Driver and everyone else must deplore in the work of the engineer—has arisen mainly from the engineer not considering art as the perfection of skilled adaptation rather than as something that may be added to, or taken from, it. The modern divorce, too, between use and beauty has been increased by the imperfect education of artists, for in the days of Egyptian, Greek, and Mediæval art no such separation existed, nor indeed was possible between scientific and artistic construction. Well may Mr. Driver point to the engineers of antiquity who constructed works of pure utility such as canals and embankments, aqueducts, roads, and bridges, which are now regarded as triumphs of architectural art. They were in fact, architects, the utility of their construction being in truth the fundamental principle of their success. There was no such a thing as engineering, in the modern sense of the word, in the days when Amiens and Salisbury Cathedrals were reared; when our old parish churches, which architects love to copy and sketch, were built. The divergence was commenced long ago, since, in fact, men ceased to bestow thought upon their work.

Mr. Driver again says, "Art in the abstract may be considered to be that which gives pleasure to the purely mental faculties, as opposed to the purely animal passions." And this view of it accords with the fact that the pleasures afforded by art are the least selfish and monopolising. Thus the pleasures of eating and drinking, and of other like corporeal appetites, are essentially monopolist pleasures; they are limited to the individual, but the beauties of art in music, painting, architecture, and sculpture, can be universally admired and enjoyed—they give pleasure to all. The author refers to the organs of sight and sound as the two mainly concerned in the æsthetic sense. The sense of "fitness" is an artistic pleasure; it produces an agreeable feeling of ease and absence of restraint, and to this source the

satisfaction of ample support in architectural construction is due. On this head the author follows, perhaps unknowingly, the recent theories of those who base æsthetics on physiology, though this division of the subject might have been amplified with advantage by reference to the theories of Spencer, Professor Bain, and many German and French writers on æsthetics, who prove conclusively the dependence of all our emotions upon the nervous organisation. The value of the principle of unity in comprehending under one simple figure, such as a triangle, circle, or square, a host of individual parts or particulars, was usefully dwelt upon by Mr. Driver before a body of engineers who, in their work, frequently fall into the mistake of multiplying detail to the complete confusion of the sense, and to the utter loss of all comprehension of plan or design.

Passing to the more practical division of the author's paper, namely, whether Engineering and Art can be united, reference was made to the service engineering has rendered to art, and Mr. Driver made a just remark that when engineering does not benefit art, it is because it has been wrongfully and improperly applied. We have, on previous occasions, argued on behalf of the same proposition, and it might be proved conclusively that every unsatisfactory work of engineering, every ugly bridge and viaduct, exhibits an imperfect or wrongfully applied principle of scientific construction. The paper dwelt upon the benefit engineering has been to art in the work of printing and engraving by the multiplication of copies, though there are a few artists who would join issue with the author upon this point. Again, in the manufacture of porcelain and glass, metal work and textile fabrics, much is due to engineering appliances, though the same exclusive and anti-liberal view of art may be held by some. In considering how art reciprocates the benefits she receives from engineering, the author pointed to the early influence of art upon engineering, which taught builders to give a gentle taper and swelling, or entasis, to the column, and to clothe the temple with beauty, and to the subsequent throwing over of art as the controlling power and master. While engineering acknowledged the master hand of art, all went well; but when modern engineering throws off the yoke of allegiance, the result has been chaos as regards art, we would rather say as regards both. The author says, and we quote this part of his paper—

The modern engineer seems utterly to ignore beauty of form; if he has to use a vertical support, he will probably make it of the same thickness all the way up; if he wants a buttress, he will put a great lump of masonry or brickwork in, without thought as to whether it will look ill or well, but calculated, I grant you, to do to an ounce what it has to do; there is an immense amount of thought in their work, but no mind,—I mean in an artistic sense; and even the thought they give to their work is of a sordid kind; for while they study how to use their material economically, they omit at the same time to study how to make their work pleasing, thus leaving half their work undone.

I admit that engineering possesses a strong point of affinity to art in its *truth*, and by this I mean the honest construction employed by engineers in their work, never disguising or hiding it, but letting it be plainly visible to all; and there is a good honest purpose in what they do, and the sentiment of reality and truth as opposed to fiction and falsehood, appealing as it does to our practical urgencies, disposes us to assign a high value to every work in which truth is strongly aimed at, and to derive an additional satisfaction in work in which fidelity of rendering is induced upon the charms peculiar to art. But while we admit and admire the truth of the engineers' work, and give them their due meed of praise for what they do, we must not forget at the same time to blame them, in that they leave so important a part of their work undone—viz., the making of it artistic. In my mind it is very nearly of equal importance that a building, a bridge, or whatever it may be, should be of good form and pleasing to the eye, as to be strong.

There is an impertinence and brutality and want of regard for the feelings of others in many of the

erections of late years—the work of modern engineers. Consider how the Thames at London has been maltreated, and I ask you, as reasonable men, what right have we to inflict on ourselves and future generations such awful examples of the selfish disregard of all that is beautiful as have there been perpetrated? Our forefathers left us, their successors, works of beauty. What shall we leave our successors!

While there is much truth in the remark that modern engineering is often brutal, or we would rather say, impolite and uncivil in its uncouth blunt honesty, we cannot agree that its forms are always the most truthful or economic, and we may cite the usual rectangular iron girder and the straight-lined iron column as instances of wasteful and imperfect adaptation.

In answer to the question whether engineering and art can be united, the author says, Yes, and by means of architecture, and proceeds to show how. "Engineering is the science of construction; architecture the art. Engineering is the hard, matter-of-fact, uneducated man of business; architecture, the cultured and polished gentleman. Architecture is educated engineering." The picture drawn of the modern engineer and architect are true: one is bold, truthful, hard, and inconsiderate; the latter, timorous, uncertain, and considerate of the feelings of others, with a desire for the beautiful, often failing from lack of power. He is "bounced and bullied out of his place by the engineer," and the author adds, much that the engineers have done should have and would have been better done by architects if they had but retained their position and kept themselves abreast of the times. In contrast with these sketches, the engineer and architect of old were one and the same individual—honest, bold, with an intense love of the beautiful. The old architect did not require the aid of the engineer in his foundations, nor did he beg the aid of anyone to touch up with a bit of gold and a few gilt bosses his bridge to make it presentable. Mr. Driver says if we are ever to hope for a reunion of engineering and art we must begin by merging the architect and engineer into one. Some apposite remarks were quoted from "Chambers's Encyclopædia" to prove that architecture truly embraces both the scientific and artistic sides of construction, and the author concluded by showing the difference in the way an engineer and an architect at present would set about the same work. The engineer would study his structure, and calculate his material to a nicety, place his doors and windows where wanted, in total neglect of artistic distribution, stick his ornament on here and there, put mouldings, not unlikely upside down, making them ridiculous; while the true architect would combine the common sense and economy of the engineer, but place his doors and windows in their most useful position, with a view to a pleasing result. Mr. Driver says, architects as a body have a far greater knowledge of practical engineering than engineers have of architecture; the "architects' failures being as nothing to the engineers' failures in art." He refers in terms of commendation to the work of the mechanical engineer in observing the rules of art, and in refusing to use Greek Doric columns for supporting the beams of engines.

Now, the author has, perhaps, rather begged the question in saying that it is by means of architecture art and engineering are to be reconciled, though it is probably the point of contact between the two professions. It is at least rather "arguing in a circle," as the logicians say, to contend that art and engineering are to be united by engineers becoming architects, or vice versa. We think the proposition sought to be established would have been better accomplished by showing the utter disintegration in the modern education of architects and engineers, and the means to be adopted in making

art instinct again take its position as the controlling impulse of the faculties employed in engineering. Until it can be clearly seen that every engineer is an uncultured artist, and every so-called architect an imperfect adapter of his materials, it will be of little use to merge the two professions. The subject is, after all, one of education: when the artist begins to find out that the pleasing effects he produces in form and colour are all derivable from impressions produced on the nerves of the eye, and when the engineer learns that his formulæ and constants are, after all, but clumsy approximations to truthful science, and that his theory takes no account of the thousand other factors of which he is supremely ignorant, there may be some prospect of a reunion between the temporarily divorced elements of engineering and art.

FINE ART EXHIBITION AT THE ROYAL ALBERT HALL.

AN exhibition of works of modern artists has been opened at the Albert Hall this week, though for what object so fashionable a locality should have been chosen, and why the Albert Hall should be turned into a fine art gallery for the sale of works of art it is not easy to imagine. To say the least, a sixpenny exhibition of pictures in so select a quarter seems hardly compatible with the original purpose of the hall. In opening the small catalogue sold at the doors we find it stated "a commission of $7\frac{1}{2}$ per cent. upon the prices quoted will be charged upon all works sold through the intermediary of this exhibition. Pictures disposed of directly by the artists themselves or through private agencies will not be exempted from payment of the conventional commission." Again, it is made known that "artists disposing of their works independently should at once announce the fact to the manager, otherwise an overt sale effected at the Exhibition will be held to take precedence over a private sale made by the artist, &c." Are we to understand by these conditions of sale that the collection now on view has been got together primarily for the purpose of sale? for if so the exhibition at once loses its ostensible character as one for the display of fine art works, and must be classed with the galleries of picture dealers and bazaars. And we may, in passing, enquire into whose hands does the $7\frac{1}{2}$ per cent. commission fall? Many of the works exhibited—or offered for sale—whichever it is—are not new to us; for instance, we see Mr. Keeley Halswelle's fine picture, hung a year or two back at the Royal Academy, entitled "Non Angli, sed Angeli" (3), portraying Gregory the Great in the market-place of Rome taking notice of the British children lying at the foot of some temple, the pitiful and pathetic countenances of whom called forth the well known inquiry of Gregory and his reply, "Call them not Angles, but angels." We see the price affixed to this picture is £800. The Queen lends a few fine works. "The Princess Doria Washing Pilgrims' Feet," by Sir D. Wilkie; "Studio of Sir Francis Chantrey," by Sir E. Landseer—the latter one of the cleverest of the artist's works. It represents a dog seated on a table covered with a red cloth, intently watching his master's interests; a cat at one corner, peeping through the partly uplifted table-cover, being the unsuspected cause of the dog's attention. "Dives and Lazarus" is a bright piece by Mr. T. Thorneycroft; but one of the finest subjects in this part of the gallery is "The Feigned Death of Juliet," by Sir F. Leighton—a grand painting, powerful in its dramatic interest, and one of the best probably ever painted by the President of the Royal Academy. A fine and impressive sea picture is Mr. J. Brett's "Christmas off the Irish Coast" (48), admirably painted in the red glow of the upper clouds and the reflec-

tion in the deep trough of sea. Mr. E. Armitage, R.A., is represented in the "Cities of the Plain," and Mr. A. J. Woolmer in the "Pre-Adamite Earth," both impressive subjects. The latter is valued at £500. Amongst many other mediocre works are two by R. Lehmann; a luminous face of the Virgin, by C. L. Desanges; a clever painting of a child in a cradle, watched over by an elder sister (5); "View of Amsterdam" (37), by Ludwig Hermann; a finely painted portrait of Mr. Geo. J. Holyoake, by W. Holyoake; and two admirable studies called "Destitute Children in London," showing the effects of a timely rescue from vice, in contrast with which is another picture of juvenile faces, "Delighted with the Gallant Pageant," by P. Hoyoll. "Sanctuary" (67), by Mr. A. D. Lancaster, is finely painted, the attitude and penitent face of the woman at the threshold of the door is pathetic and moving. "Untrodden Snow" (118), by A. MacCallum, is another old face representing the fine cedars and birch at Holland Park. Mr. J. E. Clayton, in "Birds of a Feather" (121), has given us a rather figurative treatment clever in drawing. We note also a few admirable fruit and flower pieces, Nos. 143, 150, 153, 158, 151, 156. The expression of faces in 172 in the light of gas-lamp, the office and surroundings, conspire to render Mr. W. Weekes' able picture of the "Foolish Son," a powerfully-told incident of domestic trouble. We cannot pass by Mr. MacCallum's "Cedar Grove, Chiswick," or the grand beech in Mr. W. B. Brown's picture entitled "Beechwood in Autumn." Mr. W. G. Daffarn has given us a simple reminiscence of the country in "Hours of Idleness"; the girls are well drawn, and there is a natural summer glimmer or misty light over the corn-field that reminds us of a hot day. Very touching and true to nature is "The Dark Cloud" (274), by E. C. Girardot, in which a young girl, overworked at her nightly toil, is overtaken by sleep, her head resting on a small table; the meagrely-furnished room, the cup and half-loaf, the candle burning low in its socket, and the mouse on the floor tell their own tale too powerfully to be misinterpreted. "A Belle of the Last Century," dressed in open stomacher, in the green brocade dress of the time, is a cleverly painted subject. Very clear and sparkling in tone is Mr. J. Vivian's "End of Grand Canal, Venice" (285); while for study of character Mr. Ludovici's "Singing Lesson," (304), must be awarded praise for the pose of the young maidens, and the rendering of the accessories. No. 313, "A Child of Newgate," by S. M. Louisa Taylor, might draw a tear to the eye in the touching penitence of the convict, and the sympathising expression of the sister of mercy. Portraits of Captain Sir F. Leopold M'Clintock, Captain Sir G. S. Nares, Captain Sir John M'Clure, and other Arctic explorers occupy conspicuous places in the gallery. "Westminster from Lambeth-bridge" is a fine subject for the architectural painter, and Mr. J. O'Connor has chosen a good point of view, and given us the soft haze of an August morning, and a slimy river bank; but the clock-tower of the Parliament Houses is defective in proportion. Few will not be struck with a droll picture of a little girl clad in black velvet, with a lace cross-over, apron, and red sash, with countenance of a most demure kind, a floriated screen being the background. It is by Maria Brooks.

Mr. J. Barker's "Scotch Cattle," and Mr. J. Richardson's "West Highland Cattle" are fine paintings of Northern breeds. "Elaine," by M. Burnham Brook; "A Saint's Day in an Italian Church," "A Young Heart and an Old Shoe," by H. M. Vos, jun.; some fine Swiss scenery (359, 361); "Evening on the Coast," by Caroline F. Williams (381); No. 387, "Girl at Window," an Oriental theme, clever in its painted glass and warmth of light, by R. Gavin. The

"Sleep Walker," "An Idle Housemaid," (404), by P. A. Fraser, "Amor Vincit Omnia," an allegorical picture by Walter Crane; "Crossing the Styx," by F. A. Hopkins; 443, "Lake Thun," grand rose-tinted mountain in the glow of sunset, by Mr. W. S. Morrish, are a few other pictures that are worth noting.

We cannot say much for the water-colours, though there are a few pieces of merit, amongst which are "The Matterhorn," by W. Croft; "The Eiger" (465), by J. W. Smith; "Tomb of John Mark, Evangelist in St. Mark's, Venice," a splendid blending of coloured marble, by J. Bunney; No. 529, "A Study of Pottery," in which the soft colouring and reflected light are skilfully handled by B. W. Spiers, and a few architectural subjects, notably No. 486, "Cloisters of Magdalen College, Oxford," by G. R. Clarke; "Rouen Cathedral" (587), by S. J. Hodgson; another Continental sketch at Rouen, by J. R. Barraud (589), and a pleasing sketch of the Church of St. Wolfran, Abbeville, by J. D. Barnett. In the west gallery we note No. 621, a sketch, by L. Lewis; No. 644, "Interior of St. Mark's," by Mr. Hodson; No. 679, "Llantony Abbey, Monmouth," by H. R. Cauty; "A Street Scene," by G. R. Clarke (670), &c. The etchings, engravings, and autotypes are not numerous; we may note an etching by L. B. Phillips of the Canal, Bruges; a charcoal drawing of ducks "on the wing" by G. E. Rischgitz; a few admirable engravings by R. Josey, J. Ballin, A. Blanchard, &c.; and some capital autotypes by the Autotype Company. The paintings on china plaques &c., cannot be called, on the whole, successful works of the kind. There is too great a disposition manifested on the part of the artists to produce pictures rather than suitable modes of decoration. Allegories, classical myths, and fruits and flowers constitute the chief means of ornamentation, and the best works are those with a Japanese motif. No. 803, "Romola," by E. Havers, is a cleverly adapted head with conventional background. A large plaque, set in ebony frame, by Mr. J. Sparkes, is the most striking and perhaps tasteful instance of china painting. It represents a maiden with a little girl forming a daisy chain. The flower background of daisies makes a pleasing conventional relief, and the colouring and drawing are not heavily done, but are in simple outline with light flat tints. The mistake in many of the productions is over-finish and relief, while that decorative character appropriate to ceramic subjects is ignored. "The Gamblers," after Meissonier, by L. Hall, illustrates the latter mode. One of the best examples of foliage treatment is Miss Edith Croper's "Purple Clematis"—a rich blue spray on white ground, in a Japanese style. Some decorative tiles, with birds and pear blossom, by Augusta M. Reid; "The Mermaid," by J. Cole; dessert plate, by B. A. Louis, "Autumn Brambles" (877), "Conventional Apples" (879), by J. Edith Cowper, and "White Passion Flowers" (880), by Florence Cowper, are all pleasing specimens of ceramic decoration. We have no room left to say anything upon the paintings on ivory and miniatures, many of which will repay inspection. In wood carving Mr. T. Colley sends a panel carved in limewood after Gibbons, and an oak frame. The style of the Adams is shown in a frieze, eboused and gilt, by Mr. W. M. Holmes, and a mahogany frame, by the same artist, both unique examples of execution. Some well-modelled terra-cotta busts are also to be seen in the collection, the names of J. Bell, Marshall Wood, Thorneycroft, J. Edwards, Eli Johnson, Callcott, and other artists being among the contributors.

The paintings, drawings, and designs executed by the students in the Great Yarmouth School of Art were exhibited last week and were well patronised.

ARCHITECTURAL GEOLOGY.—III.

OOLITIC OR JURASSIC FORMATION.

THE term "Oolitic" is applied to the series we are about to describe, on account of the peculiar character of the limestones which form its distinctive feature. These are composed of small round particles of calcareous matter, cemented together so as to resemble, when examined by a magnifier, the appearance of a mass of eggs or the roe of a fish, hence they are often known by the name of *roe-stones*; when, however, the particles are as large as a pea the stone is termed "pea-stone," or "Pisolite." All these limestones are full of marine shells and other organic remains, and are interstratified with sands and clays. From the circumstance of these strata being developed in the Jura range, between France and Switzerland, the term "Jurassic" is commonly applied to them, including, however, the "Lias" beds, which are usually found immediately below the Oolite. In this country the Oolite is a very important formation, as the greater part of our building stones are obtained from it. There are four principal divisions of the formation in England: (1) the Upper or Portland Oolite, (2) the Middle or Oxford Oolite, (3) the Great or Bath Oolite, (4) the Lower or Inferior Oolite, which overlies the Lias.

Portland Oolite is so named from the fact of its greatest development occurring in the Island of Portland, from which the best Oolitic stone is obtained; the quarries being worked in all parts of the island, and those on the north-east yielding the best quality, while the worst is found on the opposite side. The hardest and most durable stone is the "Roach," found near the top, but, as it contains numerous cavities left by shells, it is not so suitable for architectural purposes as the bed that comes directly below it, and called the "Whit bed," which is of a light brown colour and generally known to London masons by the name of "brown" Portland. Lower down in the quarry we come upon softer and whiter stone, which is much used by builders on account of its being easier to work than the "brown," but its crushing-strength is less by one-fourth, and, being of a more absorbent character, it is consequently more readily acted on by frost and weather. Portland stone contains 95 per cent. of carbonate of lime, with a small quantity of silica, magnesia, iron, and alumina. As a full account of this stone has been given in the BUILDING NEWS for June 12, 1874, we shall not enlarge further on the subject at present, but refer our readers to that article. The beds of this formation are found in other parts of the country, being worked for building stone in the counties of Bucks and Oxford, near Aylesbury, Headington, Garsington, and Great Haseley; at the last named place there is a bed 8ft. thick of white limestone resting on a sandy oolite. The Pendle stone found near Aylesbury is a soft calcareous sandstone. At Swindon there is a stratum of limestone 8ft. thick, with beds of hard calcareous sandstone. In the neighbourhood of Chilmark and Tisbury in Wilts we find a silicious limestone of very excellent quality, some of which is equal to the best Portland as a building material. At Sherborne, in Dorset, a sandstone is quarried for building purposes in this formation.

Purbeck Beds, so called from being developed in the Isle of Purbeck on the Dorset coast, belong to the Upper Oolite, and consist of fresh-water limestones and clays, attaining a thickness of 300ft.; the hard shelly limestone called "Purbeck marble" is obtained from these strata. The Purbeck beds are found in other parts of Dorset, as at Wareham, Kingston, and Darleston Bay near Swanage, also at Tisbury and Chilmark in Wilts, the stone procured from Chilmark

being used for roof tiles in the neighbourhood.

Middle Oolitic strata consists of sands, clay, and Oolitic limestone, of which the upper beds called the "coralline" are well developed in Dorset, being 250 feet thick near Weymouth; and a fine-grained freestone is obtained from quarries at Todbere, near Bruton, Marnhull, and Gillingham. In Wilts a building stone is quarried at Purton, near Swindon, and a calcareous grit at Seend. A Pisolitic stone is found near Steeple Ashton, and a superior quality of lime is obtained from the stone of Westbrook, near Melksham. In Oxfordshire there is a 12-foot bed of Oolitic stone in the Headington quarries, which has been much used in buildings at Oxford, as well as the stone procured from Wheatley. The lower beds of this formation are known as the *Oxford Clay*, a dark blue, yellowish or slaty-coloured clay, in which selenite and septaria are found and occasional layers of calcareous sandstone; it is worked largely for the manufacture of bricks and tiles at Peterborough, Oundle, and several places in Dorset, Wilts, and Gloucester; it is not a water-bearing stratum, and must be pierced if water is to be obtained.

Great or Bath Oolite.—This division contains large quantities of excellent freestones in great request for architectural work, together with beds of shelly limestone or rags, clay, sand, and flagstones. It ranges through parts of Oxford, Northampton, Lincoln, Gloucester, Wilts, and Somerset; what is termed Bath stone being procured from the Downs of North Wilts between Bath and Chippenham, where it is quarried by tunnelling into the sides of the hills; when found in the quarry it is soft and moist, almost crumbling at the touch and having a yellow tint, but after exposure to the air it gets white and hard as it dries. The "weather" bed, which is a brown shelly limestone, is best for the parts of a building which are most exposed to weather, but the "scallop," which has a fine texture and is of superior quality, is more suitable for carving and moulding. In the neighbourhood of Minchinhampton, Gloucester, and other parts of Gloucestershire, there are extensive quarries of Oolitic stone, and a sandstone is found at Burley, near Cirencester. The Great Oolite is also largely worked for building stone in the counties of Northampton and Lincoln at the quarries of Barnack, Casterton, and Ketton, near Stamford; Haydon, near Grantham; and Aneaster, near Sleaford. Limestone for building is obtained at Kettering, and a ragstone at Stanwick, near Higham Ferrers. A hard crystalline limestone, which takes a good polish, and is called "marble," is procured from the quarries of Alwalton, in Huntingdon. The Oolites of Aneaster, Bath, and Ketton are remarkable for the complete absence of silica in their composition, which is from 92 to 94½ per cent. of carbonate of lime, with 2½ to 4 per cent. of carbonate of magnesia, and a small proportion of iron and alumina. The stone of Aneaster weighs 139lb. to the cubic foot, that of Ketton 128lb., and that of Bath 123lb.

Forest Marble consists of a series of oolites, clays, and sand, which are chiefly found at Wychwood and Bladon in Oxford, and at Fairford, Chavenage, Milborne Port, and Wincanton; its chief value consisting in the thin flagstones and roofing slates which are procured from it. In some places, however, as at Long Burton, near Sherborne, it is hard enough to be polished as marble; it is also quarried for church-building purposes at Wormwood in Somersetshire, and at Alworth, in Wilts; at Bearfield, near Bradford in Wilts, a firestone is obtained. Beds of clay are found in this formation at Bradford-on-Avon and also at Scarborough in Yorkshire, where they are worked for making drain-pipes and tiles.

Cornbrash is a term applied to a bed of stelly limestone which occurs near Woodstock, and is used for walling and for burning into lime.

Stonefield Slates are thin flagstones obtained near Woodstock, and much used in Oxfordshire for roofing and paving purposes; and at Charlbury a sandstone is quarried which has been much used for buildings in Oxford.

The Great Oolite is quarried at several places in Somerset—being obtained near Taunton for building stone, and at Holcombe for paving; the quarries of Montacute and Bridgewater yield a sandstone used for building. In Oxford a brown shelly Oolite for building is found at Tainton, near Burford, weighing 136lb. to the cubic foot. In Northampton we find a sandstone at Blisworth, Rockingham, Oundle, and Wellingborough; and a limestone near Northampton. In the north-east of Yorkshire, this formation yields a light-brown sandstone at Aislaby, Newton-dale, and Sneaton, near Whitby, weighing about 126lb. per cubic foot, which is much used for local buildings; a freestone is also found at Oswaldkirk, near Gilling; and, at New Malton and Brough, a sandstone for building is procured, that from Brough having been employed in Beverley Minster. Below the Great Oolite in Dorset and Gloucester a bed of sandy clay occurs which is called *Fuller's earth*, from which copious springs of water can always be obtained.

Lower Oolite.—In this division we find sandy Oolites combined with beds of compact limestone, quarries of which are worked in the south-west of England, the north of Oxford, Northampton, and South Lincolnshire. The stone of Doulting, near Shepton Mallet, in Somerset, belongs to this formation, and has been much used in Wells Cathedral; Glastonbury Abbey, and elsewhere, being a light-brown, shelly Oolite, weighing 134lb. per cubic foot. Good building stone, much used in Bristol, is obtained at Dundryhill; and a ferruginous, brown, shelly limestone at Hamhill, near Yeovil, which is largely used for building purposes in the neighbourhood.

In Gloucester the Lower Oolite yields good building stone at Stinchcombe, Wotton-under-Edge, Painswick, Leckhampton, Cheltenham, and other localities in the Cotswold hills; that from Leckhampton having been used in Gloucester Cathedral, Tewkesbury Abbey, Sudeley Castle, and many other buildings in the Vale of Severn; that obtained near Painswick is of fine quality, resembling Caen stone, and is in much request for architectural work. In Dorset, this formation yields sandstone, marble, and freestone, in the neighbourhood of Sherborne. In Lincoln and Rutland it is developed as a cream-coloured marly limestone with Oolitic ragstone, being quarried near Stamford, Barnack, Casterton, Ketton, Ponton, Corby, Haydon, Ancaster, and Grantham. In Northampton a peculiar calcareous sandstone is obtained at Collyweston, Wittering, Easton, Deane, and Kirby, which, after exposure to weather, is capable of being split into thin flagstones, largely used in the locality for roofing purposes, and known by the name of "Collyweston slates."

Lias.—Underlying the Oolites, but generally classed in the same series, we find alternating beds of argillaceous limestone and clay or shale in regular layers called the "Lias," the outcrop of which forms a conspicuous band, stretching across England from Whitby and Redcar on the Yorkshire coast, in a south-westerly direction to Lyme Regis, in Dorset. Organic remains abound in this formation, which is divided into Upper, Middle, and Lower Lias.

Upper Lias consists of clayey beds with nodules of limestone, well developed in Gloucestershire at Bredon Hill and Cleve

Cloud; in Dorset at Lyme Regis; in Somerset, at Glastonbury Tor, Brent Knoll, and Dundry Hill; in the north-east coast of Yorkshire, at the Cleveland Hills, and near Whitby, where the Lias cliffs are 300 to 400 feet high of dark grey shaley clay, in which the Whitby jet is found; it is also found in parts of Leicester, Northampton, and Lincolnshire. The clay is largely used in the manufacture of bricks, tiles, and drain-pipes.

Middle Lias or Marlstone contains argillaceous limestone and marlstone with layers of sands, clays, and nodular limestone below; these beds are chiefly developed in the Cotswold hills, and are also found in parts of Oxford, Northampton, Rutland, and Leicestershire, being quarried for stone and lime; they generally yield a good supply of water.

Lower Lias consists of bands of clay and impure limestone, with a bed of blue limestone below. It attains a great thickness in Dorset, Somerset, Glamorgan, Gloucester, Worcester, and Warwickshire; it is also found in Leicester and Northampton, being seen in the cuttings of the railway between Kirby and Whissendine.

In Dorset the Lias is quarried at Castle Carey for the white and blue stones which are employed for building, and also for burning into lime; cement stones are found in the lower beds at Lyme Regis, &c. In Somerset it is quarried for lime at Bodminster and Keynsham near Bristol, and for large slabs of paving-stone at Street, Keinton Mandeville, and Knapp, near Taunton; also for building stones or hydraulic lime at Curry, Mallet, Watchet, Wellington, and Yeovil; near Langport a building stone is obtained which has been much used in building the neighbouring churches. In Glamorgan it is found in the cliffs at Sutton, Southerndown, and Dunraven, the freestone of Sutton, near Merthyr, having been used in building Llandaff Cathedral. In Gloucester the Upper Lias clay is used largely in the manufacture of bricks and tiles at Cirencester, Stroud, and Brinscomb, and the clay of the Lower Lias at Moreton-in-Marsh and Evesham. In Lincolnshire the stone of the Upper Lias is burnt into lime at Scawby, and the clay is made into bricks and tiles at Lincoln. In Rutland a superior dark, cream-coloured freestone is quarried at Ketton. In Oxfordshire the clays are made into brick and tile at Banbury, Bicester, Chipping Norton, Shipton, Deddington, and Woodstock. In Northamptonshire the Lias clay is used for brick and tile at Northampton, Daventry, Thrapstone, Blisworth, Market Harborough, Moulton, Towcester, Kettering, Wellingborough, and other localities; while near Stamford it is extensively employed in the manufacture of terra-cotta, glass and other materials being mixed with the clay to give it the requisite hardness; stone is also quarried from the beds in some parts of this county, and used as building materials or burnt into lime. In Leicestershire the Lias limestone is made into lime at Barrow-on-Soar and other localities, while at Leicester the clay is worked for brickmaking. In Worcester bricks are made from it at Pershore and Evesham, and also at Rugby in Warwickshire; the stone is quarried near Stratford-on-Avon for lime and building. In Yorkshire there are quarries of "whinstone" in the Upper Lias at Egton, near Whitby, which has been much employed in Whitby as a building stone.

The Lias formation is chiefly valuable to the builder for the excellent hydraulic lime obtained from it, which, when mixed with sand, slacks slowly, and has the property of setting under water. The term *shale*, which we have frequently used, is applied to a clay which has become hardened and laminated by pressure.

CORRECTION.—In the previous article at page 113, line 28 of the second column, for "Rugall" read "Reigate."

COMPETITIONS.

BUSHEY.—Five architects have been invited to send in designs in limited competition by the 21st inst. for the erection of a new church at New Bushey, near Watford, Herts. Messrs. Coe and Robinson, Mr. W. Young, of Exeter Hall (the architect of Oxhey Grange, the residence of one of the principal donors of the new church), Mr. W. T. Mley; Mr. Synce, of Watford; Mr. Raikes, and two other architects acting together, whose names are unknown to us, are the competitors. We believe the cost of the new church will be somewhere about £4,000.

METROPOLITAN FREE HOSPITAL.—The old premises of this institution, situated in Devonshire-square, Bishopsgate, were taken by the Metropolitan Railway in 1875 for the purposes of the extension of their line. Since that time the hospital has been located in temporary premises in Commercial-street, Spitalfields. The committee recently invited six architects to prepare plans for a proposed new building. Designs from each of those gentlemen were submitted on December 2nd, 1878, under mottoes. In order to ensure perfect fairness in the selection, the committee appointed Mr. Edward P'Anson to examine the drawings, and to report as to their various merits. The result has been that Mr. P'Anson has recommended the design bearing the motto "Ad rem," as first in order of merit, and for pre-emption, being the second best submitted, that bearing the motto "Civis" in a red lozenge. Upon opening the envelopes containing the names of the competitors, the authors of the first were found to be Mr. H. H. Collins and Mr. James Edmeston, and the authors of the second Mr. James Edmeston and Mr. H. H. Collins. These gentlemen acted in conjunction. The architects will be at once instructed to proceed with the work. A review of the designs will be found on our opening page.

WEDNESBURY.—Thirty-three sets of designs were submitted for the proposed Board school in Lower High-street, Wednesbury, and twenty-eight for that in New Town. For the former the plans of Messrs. Alexander and Henman, of Stockton-on-Tees and Middlesbrough, have been selected; and for the latter those of Mr. Elliott J. Ettwell, of West Bromwich. The Board greatly regret that their award has been so long delayed, but this has arisen from causes for which they are not in any way responsible. Certain persons who were opposed to the erection of the schools in High-street took occasion to express their views in a memorial to the Education Department, which gave rise to considerable correspondence, and while this was in progress the Board thought it right to suspend the examination of the plans.

A meeting was held at Lincoln, on Saturday afternoon, to take into consideration a proposal to form an art museum at Lincoln, on the plan of the one recently organised at Nottingham. The proposal originated with Bishop Wordsworth, who announced his intention of giving £1,000. A resolution was unanimously passed to the effect that a school of art, free library, and museum were urgently needed, and a committee was formed to take preliminary steps for the purchase of the old county hospital and grounds.

Mr. J. W. Hobbs, hon. secretary of the Croydon District Master Builders' Association, writes to the South London newspapers complaining of the administration of the Dulwich College estate. He says, "For many years past frequent and irreparable injury has been caused to builders who have taken land on the above estate, by the gross negligence shown in the signing of the leases required. I have known cases where no money compensation could counteract the injury caused. Were I the sufferer, I should know how to treat the matter, as there is such a thing as unliquidated damages."

Wesley College, Dublin, was opened on the 30th ult. It is situated on the north side of St. Stephen's Green, beside the Wesleyan Centenary Chapel. It is Gothic in style, and has been erected from the designs of Mr. Alfred G. Jones, of Dublin. The buildings are of red brick with limestone and granite dressings, and bands of blue and white brick. Over the governor's house, in the centre of the buildings, is a richly-ornamented clock-turret finished with a spire.

The parish church of Bexhill, Surrey, is about to be restored, from the designs of Mr. W. Butterfield. The church will be enlarged by 100 sittings, after allowing for the removal of three galleries, and the tower will be rebuilt. For the execution of the work the tender of Mr. Gaskin, of Canterbury, has been accepted at £4,131.

ST. MARY'S, TRURO.—DRAWING ROOM CABINET—STAIRCASE, HALL, AND DINING ROOM AT FINCHLEY ROAD—DAIRY, HIGHFIELD—HOLY TRINITY CHURCH, CLAPHAM.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ST. MARY'S, TRURO.

THIS drawing was made prior to the creation of the See of Truro, with a view to increase the size of the Parish Church, and at the same time to retain the better or old portion of the existing Church intact. The large scale drawing gives a plan and elevation of one bay of the south wall of existing church, which, with the perspective view, gives a fair representation of the character and size of old St. Mary's Church. The work is principally executed in Pentenian, a local stone, but its condition is very dilapidated. Mr. J. P. St. Aubyn, architect, is the author of the design for new work illustrated. Designs for the new cathedral, now proposed to be erected from Mr. J. L. Pearson's drawings, will be found in the BUILDING NEWS for June 21st (Mr. James Hicks's); Dec. 6th (Mr. J. M. Brydson's), and Dec. 20th (Mr. J. P. St. Aubyn's)—all in last year.

NEW DINING-ROOM, OAK STAIRCASE, AND SCREEN TO HOUSE IN FINCHLEY-ROAD, LONDON.

THE view illustrates a new dining-room lately erected at a house in Finchley-road, London, being part of extensive additions. The house having been erected in somewhat of the Elizabethan style, the new portions have been made to assimilate with it; the floors also of the new part are made to range with the formerly existing floors of the house. The dado all round the room as well as all the joinery of the doors, window, &c., is of oak well moulded. The floor is laid with parquetry of a special design, and the ceiling (which is in plaster) is designed to suit a central sun-burner by which the room is well lighted; portions of the window are glazed with stained glass, the designs being illustrative of the seasons. The staircase, which is taken from a drawing exhibited last year at the Royal Academy, is of oak. It is erected in the same house as the dining-room just mentioned, being situate adjoining a long and handsome corridor, and divided from it by the screen shown in the view. It is lighted by a lofty stained-glass window at the side and over the small window shown under the stairs. The newel of the staircase is carved, and the whole work executed by Messrs. Lorraine, builders, of Pittfield Wharf, Waterloo Bridge. The works, including both dining-room and staircase, have been carried out from the designs and under the superintendence of Mr. Henry L. Legg, architect, of Christ's Hospital, London.

DAIRY COTTAGE, HIGHFIELD, SHREWSBURY.

THIS dairy cottage is now being built for Thomas Middleton Howells, Esq., from the design of Messrs. Treasure and Son, of Shrewsbury. It is of brick walling generally, with oak framing externally, except chimney bases and lower

portion of porch and bay window, which are of Grinshill red and white rubble random stone; panels between framing are cemented, and chimney stacks are of brown Broseley bricks, the roof being covered with brown or dark strawberry-coloured Broseley tiles, with red ridge cresting. All wood framing painted black, and panels white.

HOLY TRINITY, CLAPHAM, DISTRICT CHURCH OF ST. PETER.

THIS church is about to be erected in Manor-street, Clapham-common, and in the parish of Holy Trinity. The walls will be of stock brick, relieved with bands and diapers of red brick. All the arches of doors, windows, and arcade, as well as all strings and labels, will also be of red brick. The roofs, of plain wrought deal, will be covered with blue slates, and it is proposed to make the copings of terra-cotta. The church will be seated with chairs, and will accommodate 600 persons. The church is to be built in sections, a portion of the nave up to the clerestory level being the first. The whole building when finished will have cost £1,500. Mr. J. Edward K. Cutts is the architect.

DRAWING-ROOM CABINET.

THE cabinet which we illustrate this week is from the designs of Mr. W. Galsworthy Davie, architect, and has recently been made by Messrs. Hide Bros. and Cook, of Worthing. It is principally in walnut, the panels and a few other parts being in wainscot, the whole dull polished. The lyre birds are intended to represent Music, the wren Song, and the coquette what the name implies. The carving has been executed from full-size drawings supplied by the architect.

SCHOOLS OF ART.

NOTTINGHAM.—The Nottingham School of Art still maintains its foremost position among similar institutions. At the annual meeting held on Monday week, Mr. J. S. Rawle, the head-master, reported that 3,031 drawings, paintings, designs, &c., had been sent to South Kensington for inspection. Last year 3,999 works were submitted. The decrease in number is owing to the fact, that a greater proportion of the works this year were in the higher stages. Sixty-seven advanced works were chosen by the examiners for exhibition at South Kensington Museum, being one-sixteenth of the entire number selected throughout the country. Last year 67 works were exhibited. In the "National Art Competition," the school obtained 2 out of the 9 gold medals awarded, besides 2 silver, and 4 bronze medals, and 13 Queen's prizes; making a total of 21 awards,—that is, fifty per cent. more than the average number of awards gained during the past ten years. One of the gold medals was gained for a lace design,—the other for architectural design. This is the third time since 1870 that Nottingham has won the highest award in the country for architectural design. The other national awards were given for drawing the human figure from the antique, painting still-life from nature, designing for lace and other art-manufactures, &c. 14 students received free art-studentships, being two less than last year. 45 students gained 58 third-grade prizes, for drawing and painting from the living model; drawing the human figure from the antique; painting landscape and still-life from nature; modelling the human figure from the antique and from nature, &c. Last year 51 works were considered worthy of third-grade prizes. In the advanced third-grade examinations, held in May and June last, 2 candidates obtained marks for "excellence," entitling them to receive Queen's prizes. 7 works were marked "good." 1 student passed in painting still-life from nature, 1 in drawing from the living model, 5 in an examination in styles of architecture, &c., 10 in ornamental design, and 5 in advanced perspective. Total, 22 successes, against 14, last year. In the elementary, or second-grade examinations, in freehand drawing, practical geometry, perspective and model drawing, 90 candidates were successful in 119 papers. 28 students obtained marks for "excellence." Last year 111 candidates were successful in 153 papers. 22 students obtained full certificates for having passed in all the second-grade subjects. Last year 20 full certificates were gained. In the National Art Competition for 1878, Nottingham has again taken a greater number of awards than any

other School of Art in the Kingdom. The following are the most successful schools: Nottingham, 22 awards; Edinburgh, 20; South Kensington Head Schools, 18; Birmingham, 17; Westminster (London), 13; Brighton, 10; West London, 10; Lincoln, 9; St. Martin's (London), 9; Bloomsbury (London), 8; Manchester R.L., 3; Belfast, 7; Lambeth (London), 6; Kidderminster, 6; Leicester, 5; Dublin, 4; Dundee, 4; Hanley, 4; Manchester G.S., 4; Salisbury, 4; Sheffield, 4; etc. Nottingham has taken about 1-11th of the entire number of awards distributed throughout the country, to 144 Schools of Art.

WATER SUPPLY AND SANITARY MATTERS.

FEATHERSTONE, YORKSHIRE.—On Wednesday last, an inquiry was held by Mr. John Thornhill Harrison, C.E., with reference to the application of the Featherstone Local Board of Health, to borrow the sum of £7,000, for the execution of sewerage works for the townships of South Featherstone, Preston, and Stretchouse, within this district, in accordance with plan prepared by Mr. A. W. Cross, Lond. Inst., C.E., the surveyor to the board, under the direction of Messrs. Hodson, Price, and Hodson, of Loughborough, the consulting engineers. The scheme provides for the main drainage of the three townships, the sewage being brought to one point of outfall, where it is proposed to deal with it by irrigation over 28 acres of land. Considerable opposition was raised to the scheme, principally upon the ground that the Local Board had not taken any steps for serving other townships within their district, which it was intended to rate for the repayment of the loan, and on the ground that the outfall gradients were too flat. The Inspector overruled the objections as to gradients, saying that in his opinion the best possible falls had been provided that the district allowed, and said that he should report favourably as to the scheme, and that he would also bring the matter of the other townships before the Local Government Board.

THE POLLUTION OF RIVERS.—On Monday the annual meeting of the Association for the Preservation of the Rivers of Scotland from Pollution was held in the Freemasons' Hall, Edinburgh. The report advocated the appointment of Conservancy Boards throughout the country, who should have power to take steps for the prevention of river pollution under the provisions of the Act of 1876, and suggested that the Council of the Association be empowered to petition the Government to appoint such Boards. It was resolved "That this meeting is of opinion that there ought to be in this country, as in most other countries, a department of executive, one duty of which should be to look after the pollution of rivers, and see that they are kept free from such gross pollutions as not only unfit them for their primary purposes, but convert them into carriers of nuisances in the districts through which they flow."

A brickmaker named William Mercer, out on strike, was on Tuesday charged before the Liverpool stipendiary with intimidating a labourer. The magistrate thought the case proved and decided that the prisoner must pay a penalty of £5 and costs, or suffer a month's imprisonment with hard labour. He remarked that, should any other case arise, he should not be inclined to pass them over with a fine.

The Colonial Government at Sydney have telegraphed to the Agent-General urging the importance of the London committee securing for the Exhibition effective art and educational collections and sanitary appliances. We are asked to say that communications should be addressed to Mr. Jonbert, 5, Westminster-chambers, Victoria-street. An extension of the space intended for European exhibitors has now been accorded.

Lord Penzance sat as Dean of Arches on Saturday, to decide an application by the Rev. David Williams, vicar of Llanelly, Carmarthenshire, for a faculty to create a reredos in the chapel-of-ease of All Saints, being a sculptured representation of the Crucifixion of our Saviour, in Caen-stone. After an examination of the plans, the Dean of Arches pronounced the opinion that the reredos was legal, and decreed a faculty.

The Croydon Gas Company have accepted the tender of Mr. James Smith, amounting to £2,325, for the erection of new offices in Katherine-street, from the designs of Messrs. Berney and Monday.

ARCHITECTURAL ASSOCIATION.

An ordinary meeting of the Association was held on Friday evening, the President, Mr. H. L. Florence, in the chair. The following were elected members:—Messrs. F. Nicholson, Mummery, H. O. Creswell, A. Broad, Slater, W. E. Coles, and G. Harvey. A vote of thanks was passed to Messrs. Francis Brothers and Saunders for permitting the members to go over the Grand Hotel, Northumberland-avenue, on the motion of Mr. Hayes, hon. sec., who also announced that the next visit would take place on Saturday, February 8th, to Mr. Bentley's Church, Cadogan-place, Chelsea.

HOTELS AND RESTAURANTS.

Mr. FREDERICK J. FRANCIS read a paper on "Hotels and Restaurants," illustrated by a series of plans and drawings. Opening his subject by sketching a typical American hotel housing from 1,000 to 1,200 guests in comfort, and furnished with lifts, electric bells, and telegraph wires, and all the other ingenuities of modern invention by which human labour can be abridged, Mr. Francis remarked that such vast and magnificent establishments could only be supported in populous and thriving cities, and by a people who preferred the bustle and excitement of society to the quiet and comparative isolation of household life. The growth of the modern restaurant was traced from the old-fashioned London coffee-house, and it was observed that these places of public refreshment have now reached such a pitch of elegance, luxury, and completeness as to offer nearly the same advantages as a club and at much less cost. In his lecture he proposed to explain what had been done by the firm of which he was a member in four of their works—Crosby Hall, Bishopsgate; the King's Head, Fenchurch-street; the Holborn Restaurant, and the Palmerston, Old Broad-street. In 1867 Crosby Hall came into the hands of its present proprietors; under the hands of Messrs. Francis Brothers and Saunders it underwent a complete metamorphosis, and subsequently an important addition was made on the north side. The original structure was erected by Sir John Crosby, who died in 1473, but the name of the architect is unknown. In 1640 it came into the hands of Sir John Langham, and in his time the chief encroachments on the hall were made, and the great hall on the ground-floor became a grocer's warehouse. In 1672 the upper hall was converted into a meeting-house by the insertion of a floor on the level of the original minstrels' gallery. The general ground-plan of Crosby Place shows the covering of a very extensive area as belonging to the first foundations, of which only a comparatively small part remains. Fortunately, however, all that constitutes its most conspicuous architectural merit is preserved, notably the council-room and the banquetting hall on the ground-floor, and the throne-room over the council-room on the first floor. When the present proprietors became possessed of the building it was determined to convert it into a large City restaurant, but the instructions were to carry out the works in strict conformity with the original architecture, and to call in the aid of painting, stained glass, and ornamental brass-work to produce a harmonious effect. The works to the original structure were carried out in 1868, and it was not till 1873 that the additional ground was acquired. Upon this site new buildings, in accordance with the style of the old building, were erected, faced externally with stone and with the interior decorated similar to the older structure. The council-room and the whole of the extensions are appropriated to luncheon counters. The wall space is occupied by large oil paintings, representing events in English history, and in the stained-glass windows are busts of many of the rulers of England from Julius Caesar to George I. In excavating the foundations of the new buildings a fine piece of tessellated pavement was discovered 12ft. below the street level. This has been framed and glazed and inserted in the wall facing the staircase. The floor throughout is laid with encaustic tiles, and the ceilings are panelled and decorated with Tudor enrichments, the whole overlaid with polychromatic decoration. In the banquetting-room little was needed to bring out the fine proportions and superb detail of the original building. An unsightly gallery had to be removed, but the windows were intact. The exquisite bay window, with its beautiful groined ceiling, required nothing but cleansing, as also

the fine roof, with its transverse and longitudinal ribs, and rich traceried insertions. At the north end of the great hall was the minstrels' gallery with an enriched traceried front and a four-centred lofty arch leading to a waiting-room behind. The throne-room is over the council-chamber, and has a wagon-headed ceiling divided between the main ribs by enriched square panels. Here again the work had not been tampered with, and there was little to do but to decorate. The stonework was renewed under the superintendence of Mr. Blackburn, in 1836. At that time the building had been thought to be incapable of substantial repair, and a placard was issued announcing the premises to be sold

THE KING'S HEAD TAVERN, CITY.

on a building lease. At this juncture a public appeal was made for subscriptions, and a lady, Miss Hackett, came forward and took the lease and carried out a scheme of restoration with public spirit and good taste. The mediaeval smoking-room is a parallelogram-shaped apartment, with an arched recess on eastern side. It is lighted by deeply-recessed Gothic windows and an oriel window. On the walls have been hung a series of historical paintings, and there are medallions representing the zodiacal signs. The windows represent figures of the moral virtues. The kitchen department occupies the second and third floors, and two sets of lifts com-

municate with the principal rooms. The steam-boiler serves the auxiliary purpose of warming and ventilating the smoking-room. The King's Head Tavern, at the corner of Mark-lane and Fenchurch-street, may well claim to be an example of the earliest of the houses of rest and refreshment. It had the honour of a visit from Queen Elizabeth on the occasion of her release from the Tower. She is reputed to have dined off pork and peas served in a dish and cover still to be seen at the King's Head. The old building, altered, cut about, with its inconvenient kitchen on the ground-floor, and its irregular-shaped rooms and low-pitched ceilings, was not capable of being satisfactorily converted into a spacious modern restaurant, and we were, therefore, commissioned entirely to take it down and rebuild the premises. (See ground and first-floor plans.) The site was advantageously placed for reconstruction as there is ample frontage both in Fenchurch-street and Mark-lane, and also the power of opening windows in Star-alley. A double basement was provided, as the locality is well suited for the wine trade, and the lowest story was carried to a depth of 20ft. below the street level. The vaults were erected at the outset of the works to form a proper abutment for keeping up the roadway, and fireproof flooring on Fox and Barrett's principle was adopted both for ground-floor and upper basement. The lower basement floor was asphalted, and asphalt was also laid vertically on the walls to prevent access of damp to cellars. The principal entrance is in Fenchurch-street, which leads at once into a lobby, with carved ceilings, and arched side recesses, fitted with embossed glass. On the right, immediate access is obtained to the luncheon buffet (62ft. by 20ft.), and the mural decoration adopted for this room shows what may be effected by the use of art-tile painting for internal ornament. In no building in London has art-tile painting been so extensively introduced. The whole of the work in this room, and also that on the marble staircase, the first-floor vestibule, the Queen's dining-room, and the smoking-room, have been executed by Mr. Alexander Gibbs, of Bloomsbury-street. Although the original cost is considerable, yet being of so enduring a material, and so readily cleaned, it may be safely commended for notice and adoption. In the arched recesses in the luncheon buffet, the art-tile paintings illustrate the plays of Shakespeare. The counter front, the panelled ceiling, and the gas lantern and pendants, these latter by Messrs. Verity, of King-street, Covent-garden, are all designed with special reference to the architecture of the building. Underneath this luncheon buffet, and approached from a staircase of good proportions, is the chop and grill room. It measures 62ft. by 20ft., like the room above. Ventilation is gained by windows at each end, also by a ventilating cornice all round the room, communicating with a large vertical zinc tube running to the top of the building, and connected with the flue of the grill. The whole wall surface has been lined with light glazed tiles, which are clean, cheerful in colour, allowing no home for vermin, and indestructible and permanent. Connected with this room are lavatories and other conveniences. Returning to the ground-floor, and proceeding along the corridor from Fenchurch-street, is the Silician marble staircase leading to the Queen's dining-room. This staircase is 6ft. wide; on either side the walls are decorated with five art-tile paintings, representing the arrival of Queen Elizabeth at Tilbury, her royal procession on the Thames, and the procession of Edward VI., surrounded by the Royal and City arms. The first-floor landing is lighted by a stained-glass window, representing Picard, the Lord Mayor of London, entertaining Edward of England and the Kings of France, Scotland, and Cyprus. On the walls of the landing are a series of full-length figures of famous men of the Elizabethan period. The Queen's room, approached by this landing, occupies the entire of the Fenchurch-street elevation, and is lighted by windows on this and the Mark-lane fronts. It is 60ft. by 30ft., and is one of the largest dining-rooms in the City without any internal pier or column of support. The ceiling is composed of a series of geometric panels, with foliated enrichments, and the walls exhibits a complete series of illustrations from Tennyson's "Coming of Arthur," and the "Idylls of the King." The ornamentation of the space over and around the doorway in this room is in keeping, consisting of knightly trophies,

interspersed with floral and arabesque designs. The gas-fittings are chandeliers, supplied by Messrs. Verity. The chimney-pieces, with the silvered glasses over, are of some elaboration of design, consisting of a union of oak and marble, and these were supplied by Mr. Austey, of Alpha-road. In the centre of a screen is a grill, fitted round with glazed tiles; the remaining arches are occupied by recesses for coats, and for drawing wine and beer. A spacious servery is situated on this floor in contiguity with the dining-room, and communicating by lifts with kitchens at the top of the building. On the second floor the smoking-room, 35ft. by 31ft., occupies the most important position. It is carried through two floors, and provided with a gallery all round. It is lighted with two rows of windows, and also by a very large central skylight. The walls are decorated with art-tile paintings, including illustrations of the Seven Ages of Man, and a picture of Shakespeare reading his plays to Queen Elizabeth. There are other paintings, of flowers and birds, on the gallery level. Adjoining the smoking-room is another dining-room, 31ft. by 26ft., called the Marble Room, as the walls above the dado are panelled with coloured marbles; above these are carved oak panels, illuminated with heraldic shields. This dining-room opens into a small private dining-room, 16ft. by 12ft., fitted all round with pitch-pine framing in small panels. The second landing on the grand staircase contains a window of stained glass, representing Whittington, Lord Mayor, burning the bonds of Henry V. The kitchen and scullery are placed on the third floor. In both the floors are covered with chequered plates, screwed to the boards, with white-lead and felt joints, turned up two inches all round next the wall, with overflow pipes between joists to take away any water. The walls are covered with white tiles. On the fourth floor is the larder. The large chop-room in basement has a grill stove fitted with hot closets. The flue of this, which is of iron, is carried above the roof of the building, and is surrounded by an iron case for ventilating the room. On the first and second floors are serving rooms. The whole of the closets, cutting tables, &c., are heated by steam from the boilers in kitchen. The whole of these fittings were executed by Mr. Waller, of Fish-street-hill. On same floor as kitchen is a large bakers' oven in two compartments; it weighs upwards of 40 tons, and considerable care had to be taken in the construction to carry securely this weight. Since completion, an area in the first floor, originally devoted to offices, has been appropriated as an extra dining-room. It is called the Alabaster Room, as the walls, including dados and cornices, are lined with marble, arranged as pilasters and panels. The ceiling is panelled in wood and tinted, and the floor is of oak-laid herring-bone. The angle building on ground floor (the "American Stores") is devoted to tavern business, but here the Elizabethan character has been maintained in the ceiling and all joiners' details, while the windows are of stained glass, with centre busts of historical personages. The exterior elevation is of red bricks, with Portland and Bath dressings, and is treated in Elizabethan style, with Classic details. That portion of building in Mark-lane not used for restaurant purposes is treated as ordinary street architecture. Speaking generally of this building, while it is not conspicuous for magnitude, it is considered successful in adaptation to purpose, economy of service, and ready supervision; the harmony of design has been carried through all the minor details and fittings, and were we to commence this work again we could not suggest any constructive improvement in general arrangement or practical detail. The *Holborn Restaurant* is located in premises which were successively a public bath, a circus, and an American refreshment house, and was re-constructed for its present purpose about four years since. The general dimensions are 155ft. by 140ft. The grand *salon* is 95ft. by 50ft., the grill room 41ft. by 37ft. On the first floor is a gallery all round the grand *salon*, a dining-room 55ft. by 26ft., another 36ft. by 20ft., and a smaller one. The remainder of the site is appropriated to lavatories and w.c.'s, and for private rooms and residences, and a hairdresser's shop in Holborn. Very little architectural alteration was required in the works carried out four years since, although the interior arrangements underwent an entire re-casting. The grand *salon* was refloored, new continuous sky-

lights erected along the east and west galleries, dividing partitions put up, and the large dining-room, called the Prince's *salon*, was formed by sweeping away a number of small apartments. The central lantern here is 32ft. by 16ft., and the room has the two long sides covered with silvered plate-glass. The kitchen was necessarily placed in the basement. The outlay has been considerable, but the adaptation has been pronounced successful. The *Palmerston Restaurant* forms the whole of the upper and part of a lower basement of Palmerston Buildings, extending from Old Broad-street to Bishopsgate-street. There are entrances in both streets, and a broad corridor connects the two thoroughfares. A luncheon-bar at the Bishopsgate entrance leads to an extensive range of skylighted apartments in which are billiard-tables. In the centre of the building is the French dining-room, adjoining which is the kitchen. Beyond this is the chop and grill-room, and on the opposite side of corridors the smoking-room, leading again to the billiard-rooms, and these again to the wine-bar. The reconstruction of the interior necessitated some difficult needling-up of heavy walls and chimney stacks more than 100ft. high. The cellarage in the lower basement exceeds 12,000ft. in area. Reference may be made to *Magog's* in Cheapside, a tavern where oil-paintings of a high class decorate the walls, where all the windows are filled with stained glass, and where unusual care has been bestowed on counters, gas fittings, and floors, with a result as far removed from the vulgar glare of the modern gin-palace as from the dingy rustiness of the old "public." We will pass on to notice the *Grand Hotel*, in Charing Cross and Northumberland-avenue. The area measures nearly 20,000 superficial feet. The ground-floor fronting the streets is designed for a series of thirteen shops. In Northumberland-street there will be a luncheon buffet 75ft. by 20ft.; a central dining-room 100ft. by 50ft., a secondary dining-room 41ft. by 35ft., and a smoking room 41ft. by 31ft., and 20ft. high. Under this room in the basement is a billiard-room; under the luncheon buffet is a grill-room lighted by corridors in Northumberland-street, and with wall surface laid round with glazed tiles. The remainder of this lower story is occupied by basements of shops, lavatories, and w.c.'s, luggage rooms, and subordinate offices. On the first floor are a series of sitting and bed rooms, having an average of 300ft. super., and with an approach corridor between. At the Northumberland-street end on the first, second, third, and fourth floors the space is appropriated to the kitchen department, the stores being on first, the larders on second, bakery on third, and kitchen ranges, &c., on fourth floor. On the first floor there are also a dining-room 41ft. by 32ft., and a library 21ft. by 19ft. The grand staircase, 25ft. by 19ft., extends from the upper basement to the attic. Instead of the ordinary treads and risers, it is intended that each step shall be carried by building iron joists in the walls, riveted to raking strings, and to form the foundation of the treads and risers from top to bottom, with Allen's patent concrete interlaced with hoop iron. Upon this will be fixed Sicilian marble treads and risers, mitred to cut and moulded string, and relieved with polished onyx paterae in ends of each step. On the upper flight Greenmoor stone will take the place of marble, and the strings will be in Portland cement finished with Parian. The soffits of stairs and landings will throughout be made and moulded in panels, finished in Parian cement for decoration. As the whole of the iron will be bedded-in into concrete this staircase would be a safe exit in case of fire; two hydrants will be provided on each landing. On the top floor of the hotel a large area has been reserved for the erection of a laundry, if subsequently found desirable. Independently of the large and secondary dining-rooms, billiard and smoking-rooms and drawing-room, and library on first floor, there are about 250 rooms. The character of the elevations was determined by the exigencies of the building. The curved sweep between Charing-cross and the Avenues added to the difficulty of picturesque combination, and the necessity of a sevenfold division of stories prevented massive treatment, while the very heavy ground-rent forbade sacrifice of any part of the area in recesses. The Italian style offered the least difficulty in designing, and the high mansard roofs at the east extremity of the front and on either side of the curved sweep will somewhat take off the horizontalism of the

façades. The large central dining-hall measures 100ft. by 50ft.; it will have a waggon-headed ceiling of glass and iron, with ornamental ribs, the whole double-glazed and provided with special appliances for ventilation. For the dados, pedestals, and columns used in decorating the ground and secondary saloons, veined and Sicilian marble will be used; the treatment of the panels between the pilasters is not yet determined upon. The smoking-room south of the main entrance and on the same level is 41ft. by 31ft., and upwards of 20ft. high. It will be ventilated by inlets of fresh air at the back of the skirting, by ventilating flues in the several walls, by a ventilating cornice running round the room and by the central sun-burner. The woodwork of this room will be of pitch-pine, French polished, with the mouldings relieved in gold, and the walls covered with stamped leather, paper, or æsthetic subjects on glazed tiles. The servery on ground-floor is 27ft. by 23ft., and being 20ft. high, has ample space for a surrounding gallery for various stores. The wine and beer cellars are under the grand saloon, and arrangements have been made by a separate series of air flues and pipes to regulate the temperature. The passenger lift will be worked by gearing below, the power being obtained by an eight horse-power gas-engine provided in duplicate. These engines are proposed to be the Otto silent gas-engine; when started, they require but little attention, and the cost of maintaining the same will not exceed 1d. per hour. The ordinary speed will be about 50ft. per minute; the power to be such that 12cwt. could be lifted at this speed. The ground and first floors are of fire-proof construction on Dennett's principle, the remaining part of moulding being ordinary timber girders and joists. In conclusion Mr. Francis said the hotel was, when the members visited it the previous Saturday, in a very incomplete state. When, he added, the structure approaches its completion, and we can realise the hopes formed as to the result of our labours; when the large central dining-room with its semi-circular roof, its marble columns, pilasters, and dado, and its combined silk and art-tile enrichments are finished, illuminated very probably by the electric light; when the several other reception rooms are ready with their distinctive detail and varied wall decoration; when we can walk up the marble staircase or traverse the several stories by the aid of the lift; when the multiplied cooking arrangements are in their places; when rooms are furnished and corridors completed—then it may be worthy another visit from the Association, and I shall be most happy, with the consent of the proprietors, to escort the members over the completed building, and to supplement the present hasty sketch with a better and more attractive description.

ROYAL ACADEMY LECTURES ON ARCHITECTURE.

THE GOTHIC REVIVAL AND SIR GILBERT SCOTT.

IN the second portion of the first Academy Lecture on Architecture, delivered by Professor Barry on the 30th ult. (see p. 133), the career of Sir Gilbert Scott was dealt with in reference to the Gothic revival. Sir Gilbert Scott might be considered a representative of an architectural revolution; he was a revivalist by taste as well as from conviction. He spoke of his love for Gothic architecture as "absolutely spontaneous," and he regarded Classic work as alien to our race and religion, and early in professional life identified himself with the new Gothic movement. The question might be asked, why have such violent revulsions of public opinion from the Classic Renaissance to the Gothic Revival? Why should not the progress of architecture be as gradual as in olden days, when changes succeeded each other as naturally as blooms follow buds? The answer must be that this is an age of freedom of thought. The time is past when men agreed to receive their policy, their religion, their architecture, from others. The "revival of letters" was an outburst of freedom, and if we will have liberty, we must accept its drawbacks. Those who think by repudiating revivals to obtain originality, indulge in a vain hope. Architecture is not free; she has a scientific as well as an artistic side, and must be useful as well as ornamental. A revival, if it be more than a passing fancy, must be called for by some new want to be supplied, or by some deficiencies to be atoned for. At the

time of the Gothic revival, both these conditions were present. A craving had arisen for something better than the then prevailing dreary bareness of churches, public buildings, and houses. Men began to turn to art as a civiliser and teacher; a revived earnestness in religion brought new forces into play, and everything became ripe for an architectural revival. Further, an age of ecclesiastical neglect had allowed our cathedrals and churches to fall into decay. A cry was now raised for the building of new churches and the repair and restoration of old ones, and Scott threw himself into the new movement with great energy. The movement would scarcely have advanced as rapidly as it did, if it had not been for the choice of Gothic architecture for the rebuilding of the Houses of Parliament. For this work it became necessary to train workmen for the various departments of stone and wood carving, encaustic tiles, decoration, metal work, &c. To educate workmen in Gothic principles of work, collections of casts and specimens were made, and Sir Gilbert Scott became one of the first and warmest supporters of the Architectural Museum at Westminster, an institution established with this object. The influence exerted by Pugin and his followers made itself felt in all the subsidiary pursuits which are allied to architectural design, and thus it became possible for architects to ensure the due execution of their ideas, in the style now coming into use. In secular as well as in ecclesiastical work some phase of Gothic was adopted. In the adaptation certain inconveniences were felt, and increased elasticity was desired. Some authors sought to attain these ends by mixing Italian and French peculiarities of detail with those purely English. The employment of large shafts in columns, and the partial abandonment of moulded, for plate tracery, date from this period. Sir Gilbert Scott did not, however, accept with any readiness such a modification of the revival movement. To him it was a national effort to revive the English forms of Medieval architecture. We may see traces of admixture of the foreign element in certain of his church fittings, but in his more important designs for buildings (always excepting the Albert Memorial in Hyde Park), he remained, as he began, emphatically an English architect. Neither by taste nor temperament was he an innovator. In his works we may see evidences of sobriety of taste and calmness of judgment. In his teaching in that room, Sir Gilbert enjoined a candid examination of the principles of diverse schools, and, added Professor Barry, "I cannot but adhere to this teaching, with this difference, that my distinguished predecessor's tastes had led him into the Medieval camp, while mine tend in the opposite direction. There can be no legitimate grounds for expecting success, on either hand, unless with devotion and enthusiasm, and a firm resolution to do your best." The name of Sir Gilbert Scott will ever be indissolubly associated with structures intended for ecclesiastical uses, and it is upon them that his fame will chiefly rest. No name will be handed down to our successors as much connected with recent restoration as that of Sir Gilbert Scott, and no one has been more vigorously, and, in many instances, more unjustly, assailed, in reference to this question of restoration. Mistakes will be made in all great movements. In so long, active, and laborious a career as that of Sir Gilbert Scott, episodes occurred, doubtless, which may not have commended themselves to his ripper judgment; but many of those who have been ready to listen to accusations of rashness formed an erroneous view of his character—of his painstaking habits, his calmness of judgment, his modesty, and his love for his art. A great architect stands forth before the world. His works are public property, at least as regards the right to criticise and assail them. His deeds are not like those of statesmen, lawyers, and other public men, whose mistakes are soon absolved, if not soon forgotten; nor can his failures be buried, like those of another profession. It may, perhaps, be whispered that even our greatest men do sometimes go astray; but the architect must be infallible. He is supposed to be bound to break a lance with all comers, and must be ready to defend works executed by him in the first enthusiasm of youth, as well as his achievements of yesterday. It is not necessary, however, to defend or apologise for the restorations of Sir Gilbert Scott. His works stand on their merits, and need no champion. But young architects do wisely to be cautious in

lending an ear to deprecatory anonymous criticisms. It is never difficult to find fault. The *suppressio veri* and *suggestio falsi* are twin-brothers of evil. No work of architecture that the world has yet seen is beyond criticism. How easy for any one to enumerate a string of faults, and shut his eyes, with wilful blindness, to merits and success. Criticism, to be useful, however, should be candid, and even generous. If you desire yourselves, said Prof. Barry, in conclusion, to obtain success and fame in your profession, do not believe that great reputations are lightly won, or easily supported. Do not expect that the goal is to be reached otherwise than by patient and laborious steps. Sir Joshua Reynolds declared "Students must therefore be told, again and again, that labour is the only price of solid fame, and that whatever their force of genius may be, there is no easy method of becoming a good painter." With a change of the last word, this doctrine will apply as fully to the architect as to his fellow-student. In no profession is steady application more required. You must not be discouraged at failure, and must be prepared for censure, when you have perhaps expected praise. The career of Sir Gilbert Scott was, in some respects, unique, and, in all probability, the exact circumstances of the revival which affected it can never recur. To you, as the younger standard-bearers of the profession, it may nevertheless supply encouragement. We may all determine that our noble art shall not suffer in our hands by any lack of devotion, hard work, and perseverance. Thus may we follow, though, it may be, at a distance, in the steps of the great men who have passed before, and thus may we endeavour to deserve, if it be not given us to achieve, success which may compare with theirs.

THE LOGIC OF ARCHITECTURAL DESIGN.

THE theatre of the Royal Institution was well filled on Friday evening, when Mr. H. Heathcote Statham delivered an address on "The Logic of Architectural Design." Mr. W. Spottiswoode occupied the chair. The lecture was illustrated by a series of large wall sheet-drawings; reduced copies of these, reproduced by photo-lithography, were handed as pamphlets round the room.

If I were asked, said Mr. Statham, to define in a single comprehensive phrase what is architecture, I should say, it is the art of building with expression. But, in order to proceed rightly to understand the limits and capabilities of this art, it is necessary to bear in thought that it differs from its sister arts in two important particulars. The first is that it arises out of the practical requirements of life, and must have a certain strength of construction; our houses must be such as to protect us from the weather, and so strong that they will not fall down. The other difference is that architecture has no direct reference to any of the external forms of nature. It relies in a great part for effect upon the observance of the laws of order, number, and proportion, and in this respect it rather resembles the art of music. Just as music depends on setting forth a harmony in chords of certain rates and with a definite rhythm, so does architecture. The musical theme is first displayed in the opening bars and then played with and repeated; and in the building the theme is in like manner set forth in the basement, and varied, repeated, and played with throughout the edifice. This comparison may be carried a step further; for when you have raised a line of building high enough a horizontal line is needed to indicate the termination, and so in music, when you have to repeat, a single chord is repeated several times to denote that there is no more to be expected in that direction. I believe that the fact already mentioned with reference to architecture, that it does not directly imitate the forms of nature, is one reason why there is such an absence of definite opinion as to what is right and what is wrong in architecture. If an artist should venture to depict a man with two heads, people would at once be shocked by the evident monstrosity; but if a man designed two towers or two entrances to a building which only required one, the redundancy would be just as wrong, only that the public do not take the trouble to think the subject out. What I wish to bring before you this evening is that architecture is the expression of certain wants to which it bears

a real relation. Only so long as you consider this relation of need and expression is it perfectly possible to estimate rightly whether a given building is worthy of commendation or otherwise. I don't propose, however, to evolve a logical architecture out of my own inner consciousness; I have thought it better to illustrate the progress of the art by examples on the walls, and to refer to some well known buildings as instances of what is right and what is wrong. Upon the walls you will see the elementary Doric temple of the Greeks drawn in half-elevation. You will see that it consists of a central cell enclosed in front by upright square beams; on these are horizontal beams separated from each other by short pieces of wood placed at regular intervals, and above these a raking cornice covered by roofing necessary to throw off the rain. Much of the character of the building is owing to the fact that Greece had a bright and sunny atmosphere. If this had not been the case it is very possible that the Greek column would not have existed—an illustration of the effect of climatic effect upon architecture. The first alteration to the square pillar seems to have arisen from the discovery that by taking off the corners of each post there was no diminution of the strength, while the removal of the angle allowed more light to pass through, and gave an appearance of lightness to the composition. From this point there was but a short step to giving sixteen sides to the pillar, only that when this was done, it was found that a square tile was wanted to form a firm seat underneath the beam carrying the weight of the roof, and this is the actual form in which the column appears on some well-known tombs at Beni Hassan, in Egypt. The sixteen facets hardly appeared sufficiently light, so the next process was to hollow out each of the faces, and in the earliest Doric buildings there is this simple hollowing out of a sixteen-sided pillar. But in a later phase of Greek art these sixteen "flutes" were increased to twenty, so that a point between the flutes should coincide with each angle of the covering tile or abacus. Then the column was diminished upwards—an instance of the metaphysical relation of architecture to nature. All natural objects taper from their base, and it is found that unless this rule be followed a column has a tendency to seem to be larger at the top than at the bottom. Next, a wide annulet was set between the column and the abacus, so as to form a capital, and just below this point several narrow incisions were cut round the column, with the object of stopping the upward lines and binding the whole together. These lines have aesthetically very much the same effect as the annular ligament which surrounds the wrist. Now, putting all these developments together, you get an object far more expressive of force and strength than the square pillar was; it has now a play of light and shade on its surfaces, and each decoration and ornament assists the expression. Now we come to the lintel or architrave, and this, as it has to carry the weight of the roof, is left perfectly plain. On this are set at equal distances a series of blocks, on each of which are scooped three vertical channels or "triglyphs," emphasising the fact that they bear a vertical weight. The spaces between were at first left empty, but afterwards filled with thin sculptured slabs, known as "metopes." Another beam is thrown over, and forms the lower member of a triangular tympanum or roof. The cornice projects sufficiently to keep the rain off, and is moulded so as to emphasise the construction. The whole of the building is thus seen to consist of a series of beams, and from this it gets the name of the trabeate style of architecture. The Romans threw the architecture of the Greeks into a melting pot for future ages to cast and coin from. They first brought the arch into play, although its powers had long been known. All expression was borrowed from the Greeks, and they continually used the column as a decoration although it carried no weight. Again, when they used a colonnade and strong arches together, they could not relinquish the idea that the feature must be completed by an architrave, frieze, and cornice. In modern times this fault has been frequently repeated, and London is full of instances. Another and more serious error was that in a series of round arches the line of pressure passed outside the vertical line. An arch is a system of wedge-shaped stones resting one upon the other, and kept up by the weight forcing them together at the base. In order that the arch may stand, the line of pressure

must pass within the supports, and this is not always an easy matter. The readiest way of doing it is to build thicker base walls; but this is very expensive both in money and material, and not always practicable. Another mode often adopted by the Romans was to build intersecting arches, and to throw the weight on the intervening space. When the Roman builders wished to vault in a building, this was comparatively easy if the space to be covered were square, for then they could throw cross vaults over, and the two arches met obliquely. But when they came to vault an oblong space, there was considerable difficulty. They met it by tilting the smaller arch, and the result was at the intersection of an oblique angle having a singular and unsightly twist. Against a vault they built a colonnade, and thus infringed the fundamental rule that the architectural design, both internal and external, should arise out of and express the scientific construction of the building. On the contrary, while the line of pressure from the vault is, as you will see the screen, oblique, the line of expression of the engaged column and its entablature is perpendicular. A third difficulty they met with is one which occurs in the use of the arch on a large scale in any style. When the space arched over is wide, the stones at the top become almost vertical instead of wedge-formed, and a very slight movement on the basement causes them to slip.

(To be continued next week.)

Building Intelligence.

BUCKLESHAM.—The parish church of Bucklesham was reopened on Jan. 31, having undergone restoration by Mr. W. G. Cunliffe, of Ipswich, from the designs and under the superintendence of Mr. William Smith, of 10, John-street, Adelphi, London, as architect. The cost has been about £18,000. The walls of the church throughout have been re-faced both internally and externally; in the latter case with flint work and stone dressings; while on the south side a small aisle has been added, separated from the nave by an arcade of three arches, as well as an organ chamber and vestry on the south side of the chancel. Besides the nave arcade, a new chancel arch has been inserted. The whole of the floor of the church has been raised a foot, while the chancel is raised another step, and two steps lead up to the altar. The roof is an open roof with arched pitch-pine principals springing from corbels, with moulded plates and purlins. At the west end of the nave is an oak-framed tower and spirelet in which the bell is hung. The church was formerly possessed of a west tower, and portions of the old stone-work of it were discovered in course of the restoration.

CHELMSFORD.—The new buildings of the Essex Industrial School and Home for Destitute Boys, just opened at Rainsford End, Chelmsford, were opened on Wednesday. The schools stand in an area of 10 acres, and are designed to accommodate 150 boys, besides teaching staff. The main building comprises two floors, and is E-shape on plan, with its back to the south. On the ground-floor of this longest side are placed a central entrance, and washing-room, with, on either hand, offices and stores, and offices for council. On the right of centre is the dining-room, in immediate connection with the kitchen department, and in the east wing an officers' dining-room, bakehouse, laundry, and stores. To the west of centre are lavatory and clothes-rooms in immediate connection with the playground. The west wing contains the schoolroom, 50ft. by 30ft., classrooms, punishment cells, and offices. On the first floor, over part of centre and west wing, are the workshops, reached by an external staircase and gallery from the playground, the schoolmaster's dwelling occupying the rest of the west wing. The general dormitory is 121ft. by 34ft. 6in., with an average height of 15ft., approached by staircases in centre and at east end. An infirmary, and matron's and resident officers' rooms are also provided. The building will depend for external expression entirely upon grouping and proportions. The walls are faced with stock bricks, enlivened by a few bands of red, and the roofs are covered with Major's angular corrugated tiles. The architect was

Mr. W. Stock, county surveyor; the contract for the school-building proper has been carried out by Mr. S. Parmenter, and that for the lodge and manager's house by Mr. S. Fincham, of Chelmsford. Water is supplied from a well on the premises; the chief parts of the building are warmed by hot-water pipes, supplied by Messrs. T. H. P. Dennis and Co., who gave the boiler. The total outlay has been £14,000.

ISLE OF MULL, N.B.—A new Free Church was opened at Tobermory on the 4th of January last. The style is Early English. The building, which is heated with hot-water pipes, is seated for 450, and has cost about £3,000. The architect is Mr. John C. Hay, of Edinburgh. Situated in the centre of the street which runs along one side of the beautiful little bay, the church, with its tower and spire 100ft. high, is a decided ornament to the Highland town.

METROPOLITAN BOARD OF WORKS.—On Friday this Board granted applications from the Vestry of Hampstead for permission to borrow the further sum of £1,500 for the erection of a vestry hall, and £3,000 for sewerage works. An advance of £2,000 was made to Wandsworth Vestry to purchase a vestry hall and parish offices, and one of £7,000 to the churchwardens and overseers of Bromley St. Leonard, for purchasing a site, and building a vestry hall and parish offices. A draft specification for paving works, &c., in connection with the Whitechapel and Limehouse Artisans' Dwelling scheme, were approved, and tenders were ordered to be invited.

PADDOCK.—All Saints' Church, Paddock, was re-opened on January 27, after restoration at a cost of £3,500 under the care of Messrs. John Kirk and Son, architects, of Huddersfield and Dewsbury. The old vestries and east walls have been entirely removed, a new chancel and vestries built, and the south-west porch pulled down and enlarged. These additions have been designed in the Early English style. The whole of the nave has been re-seated with pitch pine benches. The old ceiling of the church being a flat plastered one, polished pitch pine hammer beams, with tracery panelling, have been inserted. The old font has been re-dressed and removed from its original situation, and fixed in an alcove made for its reception in the tower. The ambulatory and centre aisles are laid with ornamental tiles, as is also the floor of the chancel.

PRESTON.—The Roman Catholic Church of St. Augustine, Preston, was reopened on Sunday, after improvements, carried out at a cost of £2,000. The interior has been decorated by Mr. James Smith, of Lark-hill, Preston. A new sanctuary has been added, measuring 33ft. by 30ft., and semicircular in form. Round it runs a dado of Staffordshire and Derbyshire marbles, and in them are inserted four paintings by Mr. Rossi, each 3ft. by 6ft., and representing "The Giving of the Keys," "The Raising of Jairus' Daughter," "The Taking of the Fishes," and "The Marriage at Cana." Above the dado rises an arcade in which are five frescoes, each 10ft. by 8ft., from the brush of the same artist. In the centre of the sanctuary is a large marble altar, and on the reredos is a carving of the Last Supper. The canopy over the altar rises to a height of 25ft., ending in a dome, around which cluster 6 angels in statuary marble. All the marble work, and the altar, have been executed by Mr. T. Sherrott, of Preston. The old benches in the church have been replaced by new ones of polished pitch-pine and modern design, from the workshop of Mr. Thomas Baines, of Preston.

SANDRINGHAM.—The Rectory House of Sandringham is evidently of old date, and has been added to from time to time by the various incumbents, the result of which was an incongruous pile. Last year the Prince of Wales decided to have it enlarged and thoroughly renovated internally. In pursuance with instructions, a new study and kitchen offices have just been added, a new hall and staircase in pitch-pine, and various other alterations to improve the interior. The walls are built of brick, and faced with the car stone peculiar to the locality. Some of the stoves and mantelpieces were from Messrs. Barnard, Bishop, and Barnards. The whole of the works were executed by the estate workmen, under the superintendence of Mr. C. Smedley Beek, architect, of Norwich.

SUNDERLAND.—The new church of St. Stephen's, Ayres-quay, which was erected last year from de-

signs by Messrs. Austin, Johnson, and Hicks, of Newcastle, has just been opened for public worship. The style is Gothic, of rather alate type; and the building is constructed of brick throughout, with stone mullions and tracings to the windows. The church consists of a chancel about 40ft. by 25ft., a nave 80ft. by 29ft., an organ chamber north of the chancel; and a vestry and parish room is formed under the chancel. There are no aisles; but owing to the inclination of the site a capacious schoolroom and vestry has been obtained underneath the chancel. The roof, which is very high pitched, is covered with red Staffordshire tiles, and the long straight line of ridge is broken by an octagonal bell turret above the chancel arch, of open woodwork surmounted by a lead-covered spire. The contractor for the masonry was Mr. W. Scott, of Sunderland, and the whole of the woodwork, including carved pulpit, lectern, and altar rails of wainscot, and seats of pitch pine for nearly 500 persons, is by Mr. F. Caldecleugh, of Durham. The cost of the church, including site, is about £6,500. The metal work was supplied by Messrs. Jones and Willis, of London and Birmingham.

THIRSK.—The Burial Board for Thirsk, at a meeting on Tuesday week, received about forty tenders for the construction of a cemetery, including the erection of chapels for Episcopalians and Dissenters. Each chapel will be 35ft. by 18ft., capable of seating about seventy persons, with an octagonal bier porch at the north end. The site is about 100 yards to the north-west of the vicarage, on the road leading to Newsham, the area of which is 3 acres, but more can be added if desired at any future time. The chapels will stand parallel with each other in the centre of the ground, and about 15 yards apart. There will be an entrance lodge, with Board Room. The buildings will be Gothic in character, built of brick, with Thimbleby stone dressings. The site will be enclosed with a fence wall, finished with a neat stone coping and iron palisades, and ornamental entrance gates. The whole of the works will be executed from the designs and under the superintendence of Mr. Wm. Bell, architect and surveyor, of Thirsk.

The second course of Canter Lectures at the Society of Arts this session will be by Dr. W. H. Corfield, M.A., on "Dwelling-houses: their Sanitary Construction and Arrangements." It will consist of six lectures, to be given on the following dates:—Lecture I. (February 17)—Situation and Structure of House.—Drainage of soil, foundations, walls, roof, rain-water pipes, &c. Lecture II. (February 24)—Ventilation, Warming and Lighting.—Size of rooms, overcrowding, ventilators, stoves, lights, &c. Lecture III. (March 3)—Water Supply.—Sources, systems of service, cisterns, pipes, filters, &c. Lecture IV. (March 10)—Removal of Refuse Matters.—Dust, kitchen refuse, earth closets, &c.; conservancy and water-carriage systems compared. Lecture V. (March 17)—Sewerage.—Main sewers and house branches, traps, ventilation, &c. Lecture VI. (March 24)—Water-closets, Sinks, and Baths.—Arrangements of pipes, traps, &c. The course will be illustrated by specimens and models from the Parkes Museum of Hygiene.

Dr. J. S. Phené delivered a lecture on "Cyprus" at Sion College, on Tuesday evening, in which he described the past history of the island, and the rock-cut tombs to be found at Paphos and Paphos. He stated that he had found abundant traces of sun, planetary, and serpent worship, and that the truncated mountain peaks and saurian and human similitudes traced by cairns and avenues of stones, corresponded to other remains which he had previously identified with this worship in the Western Highlands of Scotland, in Brittany, Greece, India, and with the snake mounds of America, proving the universal spread of the worship of the Enemy of mankind under the similitude of a serpent. If the cedars, pines, and cypresses which formerly clothed the island with magnificent forests were replanted, the lecturer predicted that it would soon become healthy and be blessed with more regular rain; the old harbours sought to be reopened, and the whole land restored from its present state of degradation. The lecture was illustrated by a number of water-colour sketches of scenery, plans and sections of the rock tombs, mystic caves, and serpent circles, and specimens of ceramic ware.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Twopenny, of all booksellers and news-vendors. Post free 24d. Office: 31, Tavistock-street, Covent-garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASKMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 3fr. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—B. of G. T. S. A.—M.—H. W. and Co.—M. B. of W. R. J. A.—P. O.—W. T. and Son.—M. O. T.—G. E. and Co.—D. and Co.—S. and Co.—S. T. and Co.—G. A. and Co.—W. L. B.—J. W.

A VICTIM. (We hardly see what other course is open to clients. Somebody's decision must be final, and the engineer is most likely to be the disappointed party. We quite agree with you, however, as to the frequency with which ignorant and unscrupulous people get entrusted with the direction of works; but respectable contractors should refuse to tender in such cases.) CAUTION. (He is legally entitled to the drawings.) G. L. (See Answers to Correspondents on p. 78.)

"BUILDING NEWS" DESIGNING CLUB.

J. S. (As regards your suggestion, we shall always exercise a primary regard for good construction, though the stricture you make as to the kitchen chimney in the design we published last week may be applied to hundreds of well-constructed houses. The flue is carried on an arch, and there is nothing to prevent an easy bend.)—S. Y. D. (The walls had better be battened and the tiles fixed to the battens.)—CIVIS. (We can recommend you a work by Mr. Talbot's "Ancient and Modern Furniture," to be obtained by Messrs. Batsford, Holborn.)—DRAWINGS RECEIVED.—"Agmon"—"Dunwich."

Correspondence.

PICTURESQUE ARCHITECTURE.

To the Editor of the BUILDING NEWS.

SIR,—All recognised canons of good taste and sound criticism agree in excluding from the pale of the true picturesque those foolish fabrications—constructed ruins; the sentiments attaching to intentional imperfection and designed dilapidation being utterly opposed to those connected with the effects of natural decay.

How, then, stands the case with designs, professedly architectural, in which the effect aimed at seems very analogous to that of an artificial ruin—in which discordant elements of diverse styles are linked together, as though through some accident of repair or reconstruction—in which debased Gothic and corrupted Classic unite their uncouth details in "most admired confusion," and in which features foreign to the uses of the building are dragged in neck and heels (at no small cost of money, see you) to produce novelty (aye, indeed!) and to vary outline? Is this architecture in the proper sense of the word? Is it real art in any sense?

You seem to give a decision in the affirmative under that powerful pronoun, the editorial "We," in the admiration you express for the design for

the Church of St. Michael, for the Bedford Park Estate; and if I venture in your own columns to raise debate on the point, I cry you mercy; it may be but the expiring whine of a moribund senility, so I pray you let an old crow have his croak!

On the grounds expressed above, I question this being architecture, which, as I began to learn it—alas! more than forty years ago—and have been learning it ever since, I have grown to understand as beauty and excellence of form and construction, guided by system (which implies harmony—at least, if not unity of style) and allied to utility. Perhaps I am quite wrong in such ideas of our art, and modern examples would seem to prove me so; but if perchance I am near the truth, how does such a design as that named abide the test? I will not recapitulate the characteristics which I have assigned to it, nor will I question the cleverness with which, as we might expect from its author, its very varying parts are put together. Why, however, I would ask, should a new church have a debased Tudor window at one end and a Georgian stable circular one at the other, and the bell-cot of the same stable seemingly between the two? What is the gain of that everlasting "cove" (repeated *ad nauseam* from the time of its reappearance in those City Chambers) whose effect depends on height and distance, but here brought down close to the eye? And what, in the name of all the Muses (for I forget at the moment who of them takes charge of architecture), is a "balcony" (?) wanted for on the side-aisle roof of a church? I waited with curiosity for the promised plan of this church, if haply it might give a clue as to how the balcony is to be got at, but the plan came not, and my marvel yet abides. If meeting this design in the boudoir of some worthy lady, in the shape of a paper model given by some neat-handed granddaughter or niece, one would exclaim, "How pretty," and "How funny!" and so leave it; but it is otherwise when it comes out as a serious design for execution (ominous word!)* My attempt to criticise it is ended. It may be that as a sexagenarian (and something more) I am past the appreciation of these later "revivals" (?) of 17th and 18th century "work." I confess to this, and then of course, "what can it matter what such an old noodle says?" So I had better spare my pen and your patience, and at once subscribe myself, as your readers (of the "revival") will certainly dub me,

Jan. 29th. AN ARCHITECTURAL FOGGY.

ENGLISH AND AMERICAN LOCKS.

SIR,—In your issue of the 17th ult. you comment upon a letter on above subject which appeared in the *Times*, addressed by me to the Hon. Colonel Wrottesley, R.E. In that letter I incidentally alluded to Messrs. Chubb and Son, and I notice in your issue of the 24th ult. that they traverse some of my statements respecting machine-made locks. As their remarks are calculated to depreciate the quality of the locks under discussion, perhaps you will kindly allow me a sentence or two in explanation.

I quite agree with Messrs. Chubb that it is not desirable to make a large quantity of locks with keys precisely alike; but, with all due deference to them, I cannot see that they are warranted in concluding that it is assumed by either Colonel Wrottesley or myself that "all English locks are of one class, consisting of a number of small parts, exact counterparts of one another." It does not follow, because locks are produced wholly, or partially, by machinery, that the keys should necessarily have little or no variation.

Messrs. Chubb also seem to labour under the impression that I sell the common American locks, and those only, although I stated in the *Times* that I had "no great faith" in such locks; that they were only intended for the cheap "wooden houses of the States," and that I did not buy "the purely Yankee goods." I may be allowed to say, therefore, that the special locks I sell of American manufacture differ in the keys to a far greater extent than those of the same class made in this country at higher rates. Singularly enough, it so happened that the same morning on which Messrs. Chubb's letter was published an order came by post for a school at Tunbridge for 36 of the "Anglo-American"

* I see the wood-work is to be painted green, possibly for "symbolical reasons."

locks, with keys to differ throughout, and I was able to execute the order at once from stock.

The same may be said of a large order which I executed for the War Department for Cyprus, whereas the English locks I formerly had of the same class only differed in half-dozens (or up to 6 variations) unless specially made otherwise, and at an extra price.

It is, therefore (to use Messrs. Chubb's own words), "most unfair" for them to class the "Anglo-American" locks in question among the common goods, "with little or no variation," which I had previously condemned.

With respect to Messrs. Chubb's workmen, I am pleased to find that they may be included among the "credible exceptions" quoted by me in the *Times*; but, considering that I mentioned Messrs. Chubb as one of the exceptional lock firms of this country, I really cannot see that they have much ground for complaint unless it be that they are anxious to defend the cause of their "weaker brethren," in which case their action is decidedly magnanimous.—I am, &c.,

JAMES HILL.

Upper Thames-street, London, Feb. 4.

HOUSE CLASSIFICATION AND REGISTRATION.

SIR,—We class and register our ships; might it not be a good plan and to the public advantage to do the same with our houses?

As regards drainage and water supply, a house could be classed under several heads, according to the style and quality of its fittings, e.g.—

A 1. class house has all drains, soil, and waste-pipes outside of the house, and the soil and waste-pipes and rain-pipes separate and debouching into ventilating siphon-traps at their foot, and each also ventilated properly at the top. The drain to be also trapped off from the sewer by a ventilating siphon trap, and ventilated at its higher end. All the water supply for culinary and drinking purposes to be off the main direct.

A 2.—Drainage same as above, but water supply off cisterns having no connection with water-closets, said cisterns being properly placed, and to have lids and block-tin self-acting overflows to keep out dust.

B 1.—Drains wholly or partly through house, but these and the pipes properly fitted in, trapped, and ventilated. Water supply off the main.

B 2.—Drains as in B 1, but water supply off cisterns as above.

C 1.—Drains going through house, and only partly trapped and ventilated, drain gas going up soil or waste-pipes, and not in a satisfactory condition. Water off main.

C 2.—Drains as in C 1, but water off cisterns.

D 1.—Drains going through house, and neither trapped nor ventilated properly. Water off main direct.

D 2.—Drains as in D 1, but water supply off cisterns, and so on with the other styles of fittings.

The higher classification the house would get, it would stand a better chance for selling well in the market. I have been asked to give certificates myself; but if some acknowledged standard were made out by the authorities, such would be, I believe, of immense service.—I am, &c.,

W. P. BUCHAN, Sanitary Engineer.

SEMI-DETACHED VILLAS.

SIR,—There can be no difference of opinion as to the importance and difficulty of the problem you have set before your readers, and having given considerable attention to this subject, perhaps you will allow me to indicate various points to which attention should be directed in planning, and which I find experienced tenants regard as important to the comfortable occupation of this class of houses, and as economising repairs, furniture, and domestic labour.

1. The domestic offices (including coal-cellar), should be on same level as living-rooms, and easily but not directly accessible from dining-room stairs and entrance.

N.B. A service door is preferable to a hatch, as requiring but one servant instead of two, and should be shut off from the staircase and hall.

2. The bath-room and w.c. should be distinct, easily, but not obviously, accessible; against an

external wall, but not adjoining any door or over any principal room.

3. The minimum of passages.
4. No rooms lighted from the side.
5. The minimum of external doors.
6. A roomy entrance, with space for hats and coats, and for a perambulator (this last is an important point, invariably overlooked).
7. The larder and stores should be accessible without necessarily passing through kitchen.
8. A copper in scullery (not in kitchen).
9. The kitchen range lighted from the side.
10. A water supply to bed-room floor.
11. The stairs to be screened from the front door and to be sufficiently easy of ascent.
12. A tradesmen's entrance at side.
13. A through side passage for convenience of dustmen, gardener, coal, &c.

14. The back garden not to be narrowed by too great projection of offices, or its privacy diminished by being overlooked thereby.

15. A minimum of flats and valley gutters. Sanitary and other matters, more of detail than plan, need not here be gone into.

After the well-considered design for a detached villa by "S. in a Circle," one is disappointed at his plan for a semi-detached villa, published in your number of the 31st. The plan is evidently carefully thought out, and many of the points above have been fairly met; but it remains open to obvious objections. There is no wall space for hats and coats; the back garden is narrowed to a width of 1 ft., and commanded by the servants' department; there are no less than four external doors; much waste of space in passages; all dust and garden materials must be carried through scullery; and the design could not be carried out at 6½d. a foot. The service arrangement is comically like the Irishman's bottomless sedan chair; except for the look of the thing, it would be easier for Mary, having already brought the dish and its odours into the staircase hall, to carry it through the dining-room door instead of handing it to Jane through the hatch; and although winders may be difficult altogether to dispense with without sacrificing more valuable space, yet 7½ in. riders and for-winders to a quarter space are unnecessarily inconvenient. I cannot, however, object to the scullery side-light, as the other alternative, viz., its window overlooking the garden, would be a greater evil, and in any case a tradesmen's side entrance is necessary, and the overlooking objection can be easily met by raising the division fence.

The general arrangement of the plan is probably the true one, and if the unnecessary and offensive ground-floor w.e. were dispensed with, and the entire side block brought forward, most of the objections I have named would disappear in the re-arrangement.

The problem cannot however be yet regarded as at all settled, although no doubt the attention you have called to it will bear good fruit.—I am, &c., C. M. STEDMAN.

An enquiry was recently held at Woodford, South Essex, before Mr. S. J. Smith, C.E., Local Government Board Inspector, respecting an application from the Woodford Local Board for sanction to borrow £1,800 for sewerage works.

Intercommunication.

QUESTIONS.

[5669].—**Responsibility of Clerks of Works.**—Will some of your numerous readers throw any light on the responsibility legally resting on a clerk of works? I will state a case thus:—Suppose a clerk of works having the superintendence of a building under the direction of the architect, and he is furnished with correct copies of plans, schedule, and specifications, by the architect. The clerk of works is appointed to attend to the interest of the employer in whose paid service he is, while so employed—as clerk of works—to see that the contractor fairly executes his contract according to plans, &c., and to the entire satisfaction of the architect, and according to the true intent and meaning of the plans and specifications. A clause, as usual, is in the specifications by which the contracting parties are bound to submit all disputes arising from the contract to the architect, who shall be sole arbiter between them. The contractor proceeded to execute the works, but does so totally different from the plans, and his materials and workmanship of an inferior kind, and contrary to those provided. The structure falls, and a dispute thus arises between the employers and the contractor. A reference is made to the arbiter, who summons both parties to appear before him. They accordingly appear by agent and counsel, the case is fully investigated, and the arbiter finds the contractor failed to execute the works according to plans, &c., and decides against him with expenses, and ordains him within a reasonable time (named), to take down the fallen structure and re-erect it according to the plans, &c. In the case of his failing to do so he directs the employer to do so at his expense, the architect not being paid in the ordinary way by commission on the cost of the works, but by fees. The clerk of works allowing the building to go on contrary to the plans, &c., as before stated, only reports the matter to the architect when the building gives way. The faulty building is removed by the clerk of works, at the instance of the employers (in terms of the arbiter's finding), and reconstructs it according to the plans, &c., and it is now a substantial and secure structure. The question is, On whom does the responsibility of the failure of the first structure rest?—A CONSTANT READER.

[5670].—**Laundry Drying Closet.**—I am desirous of building a drying closet to my laundry, 11 ft. x 8 ft. and should be glad if any of your readers would kindly give me some information respecting the fitting up of same, such as best method of heating, clothes-horses, ventilation, &c., or reference to any plates or drawings illustrating same. I may say there will be no room or chamber over the closet. Replies will oblige.—BAR or SOAP.

[5671].—**Storing Rain-water.**—I shall feel obliged by some reader of the BUILDING NEWS kindly informing me what size tank would be necessary to store the rain-water from about 2,182 feet sup. of roof area. I know that the rainfall for a year averages about 18 in. in depth per foot, but I am not certain how I should allow for the quantity of water taken from cistern for use of house. Full particulars will oblige.—PECKSIR.

[5672].—**Fire.**—In back numbers of this journal, questions have been asked on more than one occasion as to the means of distinguishing between the various species of fire; but the answers have, for the most part, been that practice is alone the method of acquiring it. In the Honours examination in building construction of the Science and Art Department, questions are given nearly every year which necessitate a knowledge of how to distinguish the fire when worked up. It has occurred to me that if the replies given in this journal be correct, it is manifestly unfair to give questions on a subject in which practical experience alone guides one. As I intend sitting at the coming examination, I shall be much obliged if any one will kindly help me either by giving me information on the subject, or by mentioning a book which treats of the matter.—A. S.

[5673].—**Sand Piles.**—In your "Commonplace Column," in the number for 31st January, article "Foundations," it is recommended to bore holes in the earth, and to fill those holes with sand in preference to using piles of wood when the ground is soft. This suggestion is frequently repeated in books; but in the course of a pretty long professional experience, I have never seen it put into practice, nor heard of the plan being employed.

May I ask to be informed where, and by whom, this navigable river in which I am about to make some important improvements. I should like to reduce all my levels to ordnance datum. There are several bench marks of the Ordnance Survey in my locality. Can any reader inform me how I can obtain the heights of them so as to be able to connect my levels with them.—BETA.

[5674].—**Ordnance Datum.**—I have charge of a navigable river in which I am about to make some important improvements. I should like to reduce all my levels to ordnance datum. There are several bench marks of the Ordnance Survey in my locality. Can any reader inform me how I can obtain the heights of them so as to be able to connect my levels with them.—BETA.

[5675].—**Planks, Deals, and Battens.**—Will some reader, through Intercommunication Column, inform me how to distinguish 1st from 2nd and inferior qualities of Archangel and Petersburg planks, deals and battens. They are not branded at the ends like Swedish and other goods, but merely stamped, I believe, with a small letter. Perhaps someone will also kindly inform me where I can get the weekly current prices of wood goods.—COUNTRY BUILDER.

REPLIES.

[5636].—**Porous Bricks.**—"Z. X. Y." will find that the sediment from the water will soon stop the pores in any porous bricks he can get and render them impervious. If he wants to filter the water, he should use the material of the Selenite of Iron Filtering Company.—A. W. WALLACE, M.D.

[5646].—**Condensation on Walls.**—This is of constant occurrence in the South of Ireland. It is caused by the wall getting cooled below the dew-point of the warm, moist air which comes in on a change of weather. It can be remedied by lath-and-plastering the wall, or otherwise covering it with a non-conducting substance which will prevent the cold of the wall coming to the surface, or by keeping fires in the bedroom during cold weather, so as to prevent the walls getting cooled.—A. W. WALLACE, M.D.

[5647].—**Glass.**—The glass used for white gas globes is called opal glass, and can easily be procured in flat sheets at any glass warehouse.—WILLIAM RAMSEY.

[5652].—**Cast of Carvings.**—Mr. Harry Hems' *modus operandi* should have had a little more detail, I think; otherwise the operator will find himself in "a fix" when he attempts to pull away the clay. Having prepared the clay as instructed by Mr. Hems, the operator should examine the carving, and see if there are any undercuttings; if so, they should be first filled up or squeezed, so that standing at right angles to the carving, all the surface can be seen. The exposed portion of these pieces should be dusted over by taking up dust on the end of a brush and putting it on the clay, this will prevent the general squeeze from sticking to, or disturbing the undercutting pieces, which should be taken out separately with a knife or modelling tool, and placed on the inverted squeeze in their proper places; you can then proceed as described by Mr. Hems. Should the squeeze be large, it should be covered with a coat of plaster to keep the clay from warping, and to assist in taking it away. In squeezing wood carvings, tissue paper is often used with advantage: it prevents, in some measure, the particles of clay being pressed into the pores of the wood.—H. TENAX.

[5653].—**Casting Plaster of Paris with Gelatine Moulds.**—Gelatine, I find, is best made from Russian and common glue in equal parts; to harden same, add 10% of Canada Balsam to each 1 gallon of gelatine when dissolving; in using gelatine the casts want taking out as soon as the plaster is set, as the heat of plaster, if allowed to stay in too long, will take the face off or make it soft and pappy. Allow sufficient time to cool down before refilling.—O. LISTER.

[5663].—**Plain Tile Floors.**—I have no doubt the houses referred to are very old; if so, the laths and nails will be decayed. And the mending on the roof to repair them, if not experienced men, would do more harm than good. The appearance may seem to be good. I once went on a roof of that description; but, to my surprise, the tiles and laths gave way, and I very soon found myself on the ground again more frightened than hurt. If the houses are of modern erection, the fault will most probably be in the gauge of the tiling being too great, which is often done by jerry builders. In such case, the only

cure is to strip the roof and re-lath and tile the same at a proper gauge, say not more than four inches; and properly touched underneath with hair mortar, will make a perfect cure.—PRACTICAL TILER.

Our Office Table.

THE 53rd annual exhibition of the Royal Scottish Academy was opened in Edinburgh on Saturday. The number of works exhibited is 1,078, being four fewer than last year. Among the chief pictures by members of the Academy are Mr. Herdman's "Charles Edward Seeking Shelter in the House of an Adherent," a striking illustration of the story of "Abnashar," by Mr. Lockhart, and "The Retreat from Moscow," by Mr. Gibb, one of the newly-elected associates. The pictures from a distance embrace Mr. Leslie's "School Revisited," Mr. Orchardson's "The Queen of Swords," and "The Social Eddy," and a picture by Mr. Alma Tadema, entitled "After the Audience," which occupies the central position in the great room. The president, Sir Daniel Macnee, has portraits of Sir James Bain, painted for the corporation of Glasgow, the Duke of Buccleuch, the late Mr. Samuel Bough, and Professor Balfour, of the University of Edinburgh. Among the sculptures is a marble bust, by Sir John Steell, of the late Lady Anna Stirling Maxwell, commissioned by the late Sir William Stirling Maxwell. Mr. Mossman has a colossal marble bust of the late Rev. Professor Eadie, of Glasgow; and there are also works by Mr. B. Nodie, Mr. George A. Lawson, Mr. D. W. Stevenson, Mr. John Hutchinson, Mr. Charles M'Bryde, and others. The total sum realised through the sale of pictures on Tuesday was £2,101, as compared with £1,701 on the opening day last year.

The annual conference of the General Alliance of Operative House-Painters is being held during the present week at Hanley. The meeting opened on Monday, when about fifty delegates were in attendance. The annual address was given by the President of the conference (Mr. Sumley), in which he disputed the assertion which they continually heard, that trades unionism was driving trade from the country, and prevented the development of the national resources. Arbitration was one of the fundamental principles of their society, but there were questions upon which it was impossible for them to arbitrate. He announced the accession of 1,100 members to their society during the past year, and referred to several of the subsidiary objects of the society. He said trades unionists were much indebted to Mr. John Morley for his able and exhaustive address on over-production, and to Mr. Macdonald, M.P., for introducing his Bill for compensating servants injured in the service of their employers. This Bill was of especial value to painters, whose work often placed them in jeopardy. He had not the slightest sympathy with the perpetrators of the diabolical outrages which had been committed during the recent strike in the cotton districts, and he earnestly hoped that such acts would

never again be witnessed in this country. Setting law and order at defiance must destroy the cause of any workmen.

A MEETING of artists was held on Saturday, at the Grosvenor Gallery, to consider the question of artistic copyright, as it would be affected if the recommendations in the report of the recent Royal Commission were adopted by legislation. A resolution was adopted to the effect that while the report of the Royal Commission exposed the defects of the existing law of artistic copyright, the meeting was of opinion that the interests of the public could be as adequately secured by means less injurious to the interests of art. A second resolution was also adopted as follows: "That in the absence of express stipulation the purchase or acquisition of a work of art should not carry with it the right of reproduction, but that such right should in all cases remain vested in the producer until he has specifically parted with it. It is, however, expedient for the security of purchasers and the public that this general principle should be subject to the following limitations—1. That the suggestion of the Royal Commissioners in relation to photographic portraits on commission should apply to all portraiture, and that the author of a portrait executed on commission should have no power to do anything in the exercise of his copyright without the sanction of the person who ordered it. 2. In regard to *replicas* made by the artist himself, that the possession of copyright should not be held to entitle the author of a work of art to make copies thereof in the same material, and of such close resemblance in other respects as to imperil the identity of the original work, and thereby to lessen its value." A resolution declaring that registration would prove a vexatious and ineffective mode of protection for the design in works of imaginative art was proposed by Mr. Herkomer, seconded by Sir F. Leighton, and adopted. A committee consisting of Mr. Fripp, Mr. Richmond, Mr. Albert Moore, and Mr. Herkomer was appointed to carry out the objects of the meeting. We have heard on good authority that the Royal Academy contemplate a memorial to the Government on the subject of artistic copyright.

It is proposed to establish a Society, to be called the "St. Paul's Ecclesiastical Society," for the non-professional study of Ecclesiastical Architecture and design. Members will visit churches under the direction of professional architects; frequent meetings will be held, at which lectures and papers on architectural subjects will be read and discussed. The first meeting was held in the Chapter House, 68, St. Paul's Churchyard, last night at 7 o'clock, when the rules and other matters connected with the society were brought forward for consideration. The Dean of St. Paul's has consented to become president. Mr. Penrose, Surveyor of St. Paul's Cathedral, has promised to conduct the members over St. Paul's; Mr. Randall Druee has kindly offered to give the members a systematic description of the contents of the Royal Architectural Museum, Westminster, in chronological order. Mr. R. Howard Wall is the Secretary, *pro tem*.

A MONOGRAPH, consisting of a history or architectural description and complete drawings of the Abbey of St. Andrew, Hexham, is about to be published for subscribers only by Mr. Charles Clement Hodges, of Barnsley. We have seen several of the drawings for this volume, and they bear evidence of much careful work and study. The plates (which are photo-lithographic reproductions of the author's own drawings) will comprise plans, elevations, sections, details, and perspective views both of the church itself and the remains of the domestic buildings of the abbey. The church of Hexham Abbey is equalled by none in the county of Northumberland for scale and architectural interest. Monographs of the kind now promised by Mr. Hodges deserve the support of the profession, and ultimately become exceedingly valuable records of buildings either no longer remaining or "thoroughly restored." We hope to return to Mr. Hodges' book later on.

THE important question of water supply to our large cities will, it is to be hoped, receive great attention in Parliament this session. Both Lancashire and Yorkshire will move in the matter, and the utmost efforts will be made to bring about an improvement now long demanded. Mr. Edward Howard will move for a select committee of inquiry on the subject. The scope of his proposed investigation will embrace the water supply of the manufacturing districts of both the counties mentioned. He is personally disposed to adopt whatever means may be deemed requisite to meet the existing difficulty, but before agreeing to any large measure of reform he desires full inquiry. The Thirlmere scheme attempted to be carried out by Manchester last year having drawn his attention more immediately to the subject, he will ask the Select Committee if it be appointed to decide how far it is necessary or expedient to lay the Cumberland and Westmoreland lakes under contribution. The Thirlmere scheme will again be fought bitterly, whether or not its progress delayed by the contemplated action of Mr. Howard.

MR. GLADSTONE draws attention in the *Guardian* to a plan now on foot for the restoration of the ancient and venerable, though small, cathedral church of St. German's, in the Isle of Man. The great antiquity of the see and the site may make the church, which is of the thirteenth century, seem modern in comparison; but it presents an assemblage of remarkable features which invest the scheme with more than a local character. Its restoration would fill a palpable void, as the see of Man is at present without a cathedral. The present Governor of the Isle of Man, with a view to the restoration of the ancient cathedral, has had, within the last three years, the principal arches under the central tower, together with the external walls of the building, repaired and secured under the superintendence of Mr. Anderson, well known in connection with the works at Jedburgh Abbey and the cathedral of Iona. The Governor has also obtained designs for the complete restoration of the cathedral, which Mr. Anderson estimates can be effected at a cost of £10,000.

Roofing Felts.—F. Braby & Co.

INODOROUS, SARKING, SHEATHING, AND HAIR FELTS KEPT ALWAYS IN STOCK. MANUFACTURERS OF PERFORATED ZINC, PERFORATED COPPER, AND PERFORATED IRON IN VARIOUS DESIGNS AND GAUGES.

Wrought Iron Tanks.—F. Braby & Co.

PAINTED AND GALVANISED, OF IMPROVED MANUFACTURE

HATTON GARDEN, LIVERPOOL. GREAT CLYDE STREET, GLASGOW. AND AT CYPRUS.

CHIPS.

Mr. Ruskin's costs are already raised; they are estimated at less than £400. Many working men have contributed their shilling.

A stained-glass window is to be erected in St. Margaret's Church, Westminster, in memory of the late Lady Hatherley.

The Wandsworth District Board of Works have accepted the tender of Mr. Beevers for the execution of all masonry and pavements' work in Clapham, for a term of three years, in accordance with a schedule of prices.

The town commissioners of Ennis have obtained a loan of £11,000 for the construction of waterworks for supplying the town with pure water.

The Town Commissioners of Queenstown adopted on Monday the scheme of Messrs. O'Keefe and Jackson, civil engineers, for proposed waterworks, and authorised them, in conjunction with a third hydraulic-engineer to be hereafter appointed, to prepare the necessary plans, sections, and books of reference.

A new system of water-supply was publicly inaugurated at Romsey on Thursday in last week. It has been provided by the South Hants Water Company, who have also just supplied several villages in the neighbourhood, as well as the suburbs of Southampton.

The Prime Minister has appointed Sir Richard Wallace, Bart. K.C.B., M.P., to the vacant Trusteeship of the National Portrait Gallery.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects. John Pennethorne, on "The Connection between Ancient Art and the Ancient Geometry, as illustrated by the Works of the age of Pericles." 8 p.m.
Society of Arts. Dr. B. W. Richardson, on "Further Researches in Petrographic Changes." 1 p.m.
TUESDAY.—Institution of Civil Engineers. Discussion on "The Geology and Sandhurst Water Supplies." 8 p.m.
WEDNESDAY.—Society of Arts. J. Halloway, on "An Application of the Bessemer Process to the Reduction of Metallic Sulphides." 8 p.m.
THURSDAY.—Civil and Mechanical Engineers' Society. James Lowe, on "Fracture of Iron." 6.30 p.m.
Society for the Fine Arts. C. J. Griffiths, on "The Art of Wood Engraving at the Present Day." 8 p.m.
Society of Arts. A. O. Phillip, on "Noxious Vapours." 8 p.m.
FRIDAY.—Architectural Association. R. Phené Spiers, on "The International Congress of Architects at Paris." 7.30 p.m.

HELLIWELL'S Patented NEW SYSTEM OF AIR & WATER-TIGHT IMPERMEABLE GLAZING

All Woodwork is covered, and no outside Painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

"It is suitable for Railway Stations, Mills, Weaving Sheds, &c., but is specially applicable to Greenhouses, Plant Houses, and Orchard Houses, and we should be very much inclined to try the system. It is certainly worth looking to."—*Builder*.

"And will, in our opinion, supersede any other similar system before the public."—*The London News*.

"It seems to meet the end in view more nearly than anything we have seen yet."—*The Field*.

"The patent has given high satisfaction to every one using it."—*The Christian Union*.

"Convincingly prove the new Glazing System to be worthy the attention of readers of the 'Key-stone.'"—*The Key-stone*.

For Estimates, Drawings, or Particulars, apply to the Patentee, T. W. HELLIWELL, Brighouse, Yorkshire; or, 19, Parliament-street, London.

WHITLAND ABBEY GREEN SLATES

These SLATES are of a grey green tint, are stout, and made in all sizes. A large stock available for immediate delivery. For further particulars with a list of important buildings covered, apply to the Managers, Clydesdale, R.S.O., Carnarvonshire. [ADVT.]

Holloway's Pills have many competitors, though no equals, for supplying the young and delicate with a simple, strengthening and purifying agent. These pills, composed of the finest balsams, are particularly adapted for all complaints peculiar to females, and are most serviceable at the critical periods of early and mature years.

Trade News.

WAGES MOVEMENT.

ADVERTISING.—A number of masons in this town are on strike against a proposal of the masters to lengthen the working hours by two per week.

BARNSLEY.—The Master Builders' Association of Barnsley have served a notice upon the representatives of the men's union of their intention, dating from the latter end of January, to alter both the wages and working hours of the men in the town, and this of course will affect the whole of the men employed throughout South Yorkshire. At the present time they are paid 6s. 6d. per day for five days in the week and 3s. 6d. for Saturdays. The masters propose to pay the whole of them by the

hour instead of by the day, and will ask them to work 55 hours a week, instead of 49½, as is the case at the present time. The alteration in the mode of payment, it is stated, will amount to a reduction of 4s. per week. The alteration in the scale is to take effect in May, in accordance with a resolution passed some time ago binding both masters and men.

Douling Freestone and Ham Hill Stone

of best quality. Prices, delivered at any part of the United Kingdom, given on application to CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.

Agent: Mr. E. CRICKMAY, 4, Agar-street, London, W.C.

TENDERS.

BEXHILL.—For the restoration of the parish church. Mr. W. Butterfield, architect:—
Gaskin of Canterbury (accepted) ... £4,131

BRIGHTON.—For supplying and fixing iron fence to enclose shubberies on the Madeira-road, for the Brighton Town Council:—
H. Greene and son, Brighton ... £315
Morton and Co., Liverpool ... 300
Reed and Son (accepted) ... 265

BRIGHTON.—For the construction of sewers in Prestonville, for the Brighton Town Council:—
Marshall, J. G. B. (accepted) ... £685

BRIGHTON.—For an additional story to the Sussex Hotel, Cliftonville. Mr. Fred. W. Hyde, architect, Brighton; quantities supplied:—
Cheeseman and Co ... £1,489
Lockyer ... 1,447
Garrett ... 1,380
Botting ... 1,300
Parsons and son ... 1,275
Patching and Son ... 1,186

BRISTOL.—For alterations and additions to Nos. 1, 2 and 3, Bridge-street, for Messrs. Levy and Co. Messrs. J. W. Trew and Sons, architects, 1, Wine-street, Bristol:—
Eastbrook and Sons ... £257 nett.
Giny ... 255 nett.
J. Sanders ... 248 nett.
Neale ... 245
J. Williams ... 237 nett.
J. Broad ... 205 nett.
E. J. Hatherly ... 204 nett.

[*Less £2 for revolving shutters.]

CHISWICK.—For alterations and addition to Little Sutton, Chiswick. Wm. Emerson, architect:—
Howard Bros. ... £5,404
Lasselles ... 5,331
Colls ... 5,251
Adamson and Son (accepted) ... 4,121

CROYDON.—For new offices in Catherine-street, Croydon, for the Gas Light and Coke Company. Messrs. Berney and Monday, architects:—
Coles ... £3,080
Hyde ... 2,967
Hart ... 2,790
Nightingale ... 2,760
Macey and Son ... 2,689
Smith, Jas. ... 2,525

[Architects' estimate, £2,541.]

LONDON.—For the erection and completion of a warehouse in Queenhithe, Upper Thames-street. Mr. H. H. Bridgman, architect; quantities by Mr. Walter Barnett and Mr. F. Thomson:—

THE BUILDING NEWS.

LONDON, FRIDAY, FEBRUARY 14, 1879.

OCCULT PRINCIPLES IN DESIGN.

THE Institute last Monday was occupied in discussing two subjects, each of which had more interest for the archaeologist and theorist than the practical architect. The topics, though widely different, had yet some sort of a relation. In one case the question of planning and one or two abstruse points turned on an old mediæval church, whose foundations, long since buried and forgotten, have recently become a theme of interest; and in the other case, with regard to buildings whose ruins, upwards of two thousand years old, still stand on the rock at Athens, and attest for all time a wonderful era of civilisation and refinement. Now, regarded from a practical standpoint, no one cares an iota as to the precise position or divergence of the axial lines of the old and new cathedrals of St. Paul's, or whether the choir was deflected for symbolic reasons or not; neither, on the other hand, does the practical architect care whether the proportions of the Parthenon were adjusted to the eye from certain points of sight on the Acropolis, as assumed by Mr. Pennethorne. Notwithstanding this indifference, the subjects possess some interest, and we are surprised a larger audience of the younger members of the profession was not present. They were not, perhaps, inviting topics, nor was the manner in which Mr. Pennethorne's theory was illustrated the most intelligible to those who had never before grappled with the problem.

With regard to the question of the decoration of St. Paul's, we have already said sufficient about the objections which forbid a piecemeal scheme, particularly the project for the mosaic embellishment of one part, and that the crowning feature of the cathedral. Our opinion was supported at the meeting by more than one speaker who questioned the propriety of coloured decoration in the dome and the effect it would have in "bringing down" apparently the dome over the still undecorated interior. The partial decoration contemplated, must in the mind of most artists we believe, have the effect we have before feared of destroying the natural scale of the whole building, and throwing it out of harmony; apart from the other question of expediency of beginning with the purely decorative work when so much else needs consideration. With respect to the question of the plan of Old St. Paul's, Mr. Penrose's paper, a report of which we have given, opens up a somewhat occult question, though it also shows how inaccurately the old plans were drawn that out of four extant documents not one agrees with the scale which the recently-discovered cloisters have permitted to be made, and no two agree with each other. In each of them the proportion between nave and choir varies, though Mr. Penrose strongly points to the trustworthiness of the Oxford No. 1 plan, which shows both cathedrals, and which accords fairly with Hollar's. Then there is the more interesting point as to the different directions of the axes of the old cathedral and the new, and the deflection of the choir and transept of the former from the true lines. These points can only be cleared up by an investigation of the actual foundations so far as they can be discovered, and the conclusion we can draw from them must remain more or less conjectural and uncertain. Doubtless, however, symbolic reasons lie at the bottom of the divergences of the axes.

When we come to Mr. Pennethorne's theory respecting the apparent proportions or the visual heights of the Greek temples we have something far more definite and satisfactory, for we know that the Greek architects were masters of æsthetics, and that geometric or optical principles, instead of symbolic ones, controlled the design. The subject was less intelligibly illustrated than it might have been, though some large diagrams, and a few excellent water-colour drawings of the temples by Mr. Phené Spiers were hung on the walls. We may simply explain that Mr. Pennethorne's theory is essentially founded upon optical principles. It is well understood that the geometrical elevation of a building is seldom seen in the actual proportions except from a distant point of view; the actual heights of the various parts, as seen by the eye of a spectator from a certain point of view, subtend smaller visual angles as they rise above the level of the spectator. This the Greek architects foresaw and, according to Mr. Pennethorne, they made certain corrections and adjustments of the real heights of columns, entablature, &c., as laid down by canons in the executed building. They, in fact, worked to a scale of apparent proportions after having fixed upon certain commensurable geometric quantities. Mr. Pennethorne, in his elaborate work on the "Geometry and Optics of Ancient Architecture," speaking of the Egyptian and Greeks, says:—"To prevent any apparent disturbance, either in the proportions or lines, it was found necessary to introduce certain corrections in the vertical as well as in the horizontal lines of the first masses." It does not require any great discernment to understand this requirement. It was necessary first to determine the most general point of sight from which the temple was seen, and the most favourable visual angles were chosen. Let us illustrate a case. In designing such a temple as the Parthenon there was a canon of proportion agreed upon for the width and general heights founded upon certain aliquot parts of the length of the upper step of portico. In the Doric porticoes, we are told, the whole height is found to divide into 9 aliquot parts—namely, height of steps=1 part, column=6 parts, and entablature=2 parts. Having thus obtained the actual heights of elevation, the Greeks from these calculated the *apparent* vertical magnitudes, so that they should be all commensurate with one another, and these were calculated by trigonometry, so as to suit a favourable visual angle. It is not necessary here to detail the method, as Mr. Pennethorne's paper will be found reported elsewhere, but from the above explanation we trust our readers will see the *rationale*. To say the least, the theory is highly probable, as evidence is not wanting from the writings of Plato, Aristotle, and Vitruvius, and other authorities to show that a point of view was invariably chosen by the old architects from which they considered the proportions of their buildings. Again it has been shown by Mr. Pennethorne that the calculated quantities so obtained agree very closely with the actual measurements of the temples. Of course, before the calculations can be made it is necessary to define the proportions, next to assume a horizontal plane and a point of sight in it, and the diagonal of temple or building will give the greatest view the eye can take in. The lineal heights are then obtained. To apply the corrections to the building we may assume an arc struck from the eye as a centre at the required point of view, then lines drawn through the points of division of the arc till they cut the vertical plane of building will give the corrected proportionate heights. In the case of the Parthenon the points of sight selected were two, according to this theory—namely, the south-east and north-west angles, and the results of the calculations

of these angles show a perfect agreement, Mr. Pennethorne says, between the measured and the calculated dimensions. The same agreement is affirmed between those made for the Propylæa and the porticoes of the Erechtheum.

Another part of the paper dealt with the curvature of the horizontal lines, and here the author's ideas do not quite accord with Mr. Penrose's investigations. The convexity of the lines are executed practically as arcs of circles. Referring to the Parthenon, the curvature of upper step = 0.37 by calculation, and by Mr. Penrose's measurement 0.366ft. This is a close approximation. He found the ordinates derived from measurements of steps agreed with those obtained by calculation of arc of circle. The upper step and architrave, according to Mr. Pennethorne's diagrams, have the same convexity, namely, .22, while on the flank it is .37. In the temple of Theseus, the calculated convexity of line of the upper step amounts to .065, and this is the degree of curvature adopted for all horizontal lines of portico. In the Theseum the lines are flatter than in the Parthenon (see "Geometry and Optics"). The quantity .22 regulates all horizontal lines of the last temple. We may remark, however, that Mr. Penrose found in the fronts of the Parthenon a curvature on plan, as well as in a vertical plane; thus the architrave of east front is found to bend inwards, but this has been proved by the same able authority to have resulted from accident, and not design. The only objections, indeed, to urge against the curvature of the horizontal lines are to be found upon the plea of disturbance by earthquake or otherwise; but, before such an argument can be used, the disbelievers in these corrections must account for various other refinements, such as the convergence of the axes of the angle columns, and the curvature of other lines not affected by any such causes. The subject is one that will repay study, and we refer our readers to the report of the paper itself for information, and also to Mr. Pennethorne's exhaustive work on the subject. If the theory of angular correction be not conclusively proved, it is at least based upon a very sound hypothesis, and one which the practical architect will do well to regard in the design of his buildings.

ARTISTIC COPYRIGHT.

SO many people have said so much about the law of artistic copyright during the past few days that by ordinary persons the matter has come to be considered involved to a degree which is certainly not the case. Everyone is pretty well agreed as to the badness of the existing law, which robs both artist and patron of the copyright unless one or both of them are careful to secure it. As matters stand, a copyright in a picture or drawing (not executed on commission) can exist only in those rare instances when at the time of the sale either the artist or the purchaser of the work stipulates for it by a stamped agreement. If this step is not taken the copyright lapses, and any person who may steal a photograph or copy of the picture may engrave therefrom, and sell the engravings without any fear of disturbance either from the artist or the purchaser of the picture. Many people are altogether ignorant that this is the case, but it is so nevertheless, as many an art patron has found to his astonishment and indignation. The recent Report of the Royal Commission on Copyright proposed to end the anomaly by vesting the copyright, in the absence of any special agreement, in the purchaser of the picture. This view, naturally enough, has been demurred to by artists, and one result of the dissatisfaction felt was the late meeting at the Grosvenor Gallery, to which we referred last week. The Royal Academy has probably done more good by the publication

of a memorial on the subject presented to the Government, in which the history and present position of the law of copyright is carefully considered, and in which the objections to the recommendations of the Royal Commissioners which must suggest themselves to any reasonable mind are fairly and temperately urged. The *Times*, in a somewhat shallow article, accuses the Royal Academicians of putting forward "pleas for special treatment," the fact being really quite the reverse. The memorial is a protest against the "special treatment" which, for some reason difficult to discern, it is proposed to mete out to painters. While the Royal Commissioners have decided that the right to dramatise a novel should be reserved to its author, that the fullest rights shall be reserved to sculptors, extending not only to portraits, but to copies of ancient or other works, and over photographs and drawings made of their works, and to photographers as the customary proprietors of the negatives; painters alone are to be robbed of their copyright for the benefit of the purchasers of their pictures. These recommendations have been made by a body of gentlemen exceedingly well able to guard the interests of literature and music, but without having one amongst them to represent the claims of Art, and the result is that if the outcome of their labours ever becomes law the injustice which is admitted to exist at present in connection with this matter will be indefinitely intensified.

The arguments set forward in the memorial of the Royal Academicians on behalf of the painters are just and weighty; but we attach little importance to them in comparison with the public interests, which we believe will be jeopardised if the recommendations of the Royal Commissioners are carried out. When an artist's ideas are carried beyond the original, that is to say, for instance, when engravings of a good picture are multiplied, who else but the artist may be safely trusted to watch and aid the process with an interest above mere pecuniary considerations? Will anyone who really hopes for the education of the popular taste be content to leave the matter in the hands of the mere speculator, whose chief care will be to reduce expenses to a minimum and to earn a high profit. There are artists, undoubtedly, with whom such considerations have had but little weight, but little good or harm is likely to result from the misrepresentation of their works. In the case of one who is an artist in reality—who has spent his best efforts in the achievement of a result which he knows is honestly worth far more than the price paid for its original embodiment in the hope that by-and-by its reproduction may bring him fairly-earned fame and profit, it seems hard that his conscientiousness must be punished in the way it certainly will be if the copyright laws are amended after the fashion at present proposed.

There is another right claimed by the Academy Memorial on behalf of artists which is most important and just—viz., that in the event of the sale of the copyright by the painter, the transaction should not prejudicially affect his ownership of the sketches and studies connected with the picture in question. As the law stands, the right to use these sketches and studies passes from the artist with the copyright of the finished picture; if, therefore, as is proposed, the copyright became, as a matter of course, the property of the purchaser of the picture, the artist would during the remainder of his life use in fear and trembling much of the accumulated work of previous years in the shape of sketches and studies. The Royal Commissioners have indeed perceived this, and have themselves suggested a special enactment for the protection of the painter; the wonder is that their sense of its necessity has not indicated the unnatural character of

their main recommendations, which are, as they admit, opposed to the unanimous opinion of the whole body of artists throughout the country.

We trust the Memorial of the Academy may be supported by outsiders generally, especially by the architectural profession. Architects are too well used, it is true, to the abstraction by others of ideas which no copyright Act can ever protect, and the distortion of which we are compelled to witness with weeping and gnashing of teeth; but that does not in any way affect the justice of the claims set forward by our artist brethren. There are, moreover, some special reasons which we need not refer to here, but which will occur to any of us who have to avail ourselves of their co-operation in the adornment of our works, which should induce us to support the conclusions arrived at in the Royal Academy memorial which we append:

1. The copyright in paintings and drawings to belong to the artist, but carrying no right to disturb the purchaser or owner of the picture.
2. The purchaser or owner of a picture or drawing to be protected against replicas that should so colourably imitate such picture or drawing as to reasonably allow its identity to be challenged.
3. The commissioner of a portrait picture to be protected against copies of any size, and in any material. Also to be protected against the publication and sale of engravings, or prints of any kind, or of photographs from the said portrait.
4. In the event of his sale of the copyright in a picture or drawing, the artist to be protected against such sale affecting detrimentally his full rights of property in all studies and sketches connected with the work in question.
5. Sculptures as per Royal Commissioners' report.
6. Engravings as per Royal Commissioners' report, but to be protected in all international conventions.
7. Registration of paintings and drawings not to be required until the legally-defined owner (the artist) parts with his copyright.
8. Registration of sculpture to be the same as in the case of paintings and drawings.

ON THE NORWEGIAN ORIGIN OF SCOTTISH BROCHS.

THE above title is the heading of a small pamphlet—a reprint from the "Proceedings" of the Society of Antiquaries of Scotland, by Mr. James Fergusson, in which the author endeavours to prove, in opposition to the opinion expressed in a paper read before the Scotch Society by Mr. Anderson, that the Brochs found in the north-western parts of Scotland were built by the Norwegians.

In 1876, Mr. Fergusson wrote a short essay "On the Brochs in the North of Scotland," which has since been published; and Mr. Anderson, the Curator of the above society, has lately written a rejoinder thereto in the "Archæologia Scotica," in which he contends that these towers were "all erected by the Picts not earlier than the fifth, nor later than the ninth century. Mr. Fergusson, in the pamphlet before us, answers Mr. Anderson's reply at some length; and his arguments are generally sound. He says, very truly, "The great tendency of controversies of this class is to get smothered in detail, and to such an extent as to obscure the main facts at issue." Mr. Fergusson confines attention to the essential peculiarities of the Brochs, and to the internal evidence they afford. He remarks "the one great fact which it is indispensable should be borne in mind in order to appreciate what follows, is that the Brochs are essentially works of fortification, and can only be understood when treated of according to the known principles of military science. Fortunately, whether applied to castles, citadels, or towns, these are few and simple and nearly identical in all ages and countries." From the earliest times, observes the author, through all the middle ages, and down to the curiously complex system of the present day, "none of man's architectural works have been subject to such rigid and unchangeable laws of utilitarian use as works

of fortification. Use, and use only, governs every form and every detail. . . . If, consequently, the Brochs are works of fortifications—which no one doubts—their age and uses ought to be easily ascertainable by the application of the same rules which govern all other works of their class, and it is, I believe, because they have not hitherto been looked on from this point of view, that any uncertainty exists regarding them." Mr. Fergusson further observes that no extraneous evidence has been found pointing to any date or origin. In reply to the argument that the Brochs cannot be Norwegian, because there are no Brochs in Norway, the author, with justice says, the same argument may apply to all other countries. "It may be argued they are not Celtic because there are none in Celtland except four; there are none in Pictland, though that was inhabited by Celts much more nearly approaching in condition and position to the inhabitants of Brochland than the Norwegians."

From such arguments Mr. Fergusson shows that these erections are due to some circumstances peculiar to the north-western part of Scotland. As regards their being built of stone, it was not likely in this part of Scotland, treeless as it is, they would have been built of wood, when rocks of sandstone or schistose slate existed close at hand. The peculiarity of this form of architecture is attributed by Mr. Fergusson to the presence of the Northmen or Norwegians in these countries. Either, it is maintained, the Brochs were built by the Celts to defend themselves and their country against attacks of the Norwegians, or they were erected by the Northern people to defend themselves against the Celts. As regards the precise date of the Brochs, the author does not inform us, though their distribution is given by Mr. Anderson as follows:—Shetland 75, Orkneys 70, Caithness 79, Sutherland 60, Ross Mainland 10, Isle of Lewis 28, Inverness 6, ditto Islands 41, Forfarshire 2, Perthshire 1, Stirlingshire 1, Berwickshire 1; total 374. Mr. Fergusson says the line of the Caledonian Canal divides Scotland into two parts, and we have 400 or 500 brochs on its north side, and four at the utmost on its south side. Eden Hall, Berwickshire, is not considered a true broch, and the other four in Pictland are explained by the author; at least, the four or five are considered exceptional. Mr. Fergusson thinks, from the above unequal distribution of these towers, that they were built by the Northmen themselves, for it is difficult to see what difference existed between the Celts on the two sides of this division. Hence the conclusion that "Norwegian Scotland is identical with the land of the Brochs, and that either they or the Celtic inhabitants of that region whom they dispossessed built them." While admitting the capabilities of the Celtic race, Mr. Fergusson thinks that during the Broch period (500 to 1000 A.D.), the Celts were in a very low stage; they were always gregarious, and he implies they never could have in this Highland district have risen to the high degree of civilisation the builders of the Brochs must have reached.

Discussing the theories of erection, the author describes minutely a typical Broch on the island of Mousa. It is a tower 50 feet diameter at its base, and now in parts over 40 feet high. At its inner floor line its court is 20 feet diameter, its walls 15 feet thick, honeycombed with galleries and bee-hive apartments. There are 3 of the latter on the ground-floor, and 6 of the former, one above the other, a staircase in the thickness of walls giving access to each, and also to a bartizan on the top of walls. (See Sir Henry Dryden's detail drawings in the "Arch. Scot." Vol. V.) It shows a high degree of constructive skill and is capable of holding a large garrison with stores. It is contended that a tower of this kind could not have been built by a

fisherman population, or by those engaged in agricultural or pastoral pursuits; the island must have been populous and wealthy to have required such a fortress, while the position of the tower, within 80 feet of the shore, and with its entrance turned towards the sea, makes it very improbable that the Celts could have erected it. On the other hand, if we suppose the Broch on Mousa to have been built by the Norwegians or Vikings, as suggested, the tower and its position are intelligible. The Shetland and Orkney islands were a convenient stepping stone to base further operations against the British islands, and this little island was most suitable for a settlement. No fortress, the author says, was more ingeniously contrived for defence to resist inland and foreign invaders, and the exigencies of the Vikings' life were met in the construction of these towers so exceptional in their design. It is not necessary here to enter into further details, though historical facts are equally strong against the Celtic theory. These Brochs, moreover, are situated at a distance from each other, so that they could not afford mutual support. Some of these towers were afterwards converted into farmhouses by secondary occupation, and the materials of others were used in buildings. Mr. Ferguson gives some illustration of a class of sepulchre in Scandinavia, bearing on the subject of Brochs; one is a plan and view of a dolmen at Uby, built of large boulders. In conclusion, the Irish Round Tower appears to have been a modified Scottish Broch, erected to meet other requirements. The Cloitcheachs or Round Towers were erected for defence, but afterwards may have been turned into belfries; and Mr. Ferguson thinks that an investigation into the age and uses of the Brochs will furnish the only key for the solution of the mystery still hanging round the origin and use of the Round Towers of Ireland.

THE ROYAL SCOTTISH ACADEMY.

THE fifty-third Exhibition of the R. S. Academy has been opened a fortnight earlier this year, and without the usual flourish of trumpets in the form of after-dinner speeches. The banqueting scene was dispensed with in consequence of the great loss sustained in the death of two such eminent members as Paul Chambers and Sam Bough, who were both unexpectedly removed from the field where they had won so much renown for the Academy and Scottish art.

The exhibition is considered as being a good collection, comprising some works of the very highest order, and great numbers of more than average interest and excellence. Mr. Lesly's well-known picture of "School Revisited" has evidently the widest circle of admirers. Alma Tadema has sent a work entitled "After the Audience," in which is represented an incident in the daily life of the great Roman Agrippa. This gentleman is interesting to the architect in having done something to help his great patron to turn the bricks of Rome to marble, and the painter has succeeded wonderfully in delineating one of the marble halls of the Imperial City. The texture of the surfaces and aerial perspective of the scene are rendered with a photographic accuracy of detail in the light and shade, which is really marvellous. Agrippa, who is made more of a veteran than his not very lengthened career would lead us to expect, is ascending a broad flight of steps, while a crowd of suitors watches with eager glances his retreating form. In the distance is an inner court, in which a crowd is gathered, among whom the lectors are conspicuous; and a great charm of the picture is the contrast between the shady light on the foreground of marble and the brilliant illumination of the distance, beyond which again there is a glimpse of blue through an open doorway. The picture is full of interesting study in many other aspects. The late Paul Chalmers and Sam Bough are well represented. Sir Noel Paton sends only a small study for his larger picture of "The Adversary." It is a very realistic conception of his subject, with

a serpent wriggling in burning lava at his feet. Whether he is about to "take a thought and mend" or not is left doubtful; but it is quite safe to say that Sir Noel has not made his "Satan" a hero. Mr. Herdman has a large painting of an imaginary incident in the adventures of the fugitive Prince Charlie. It is a scene of cottage life, when the gudewife pays homage to her unexpected guest, whose "duddies" bear token of his having come through many thorns and briars on his way. Mr. Gibb's picture of the "Retreat from Moscow" gives a good representation, without overmuch of sensational horrors, of the dark, dreary winter of that dismal march.

The water-colours and sculpture are not remarkable in containing much of any great interest this year. As far as commercial prospects are concerned, it is satisfactory to be able to state that the receipts of the opening day for 1879 considerably exceeded those for 1878, and amounted to over £2,000.

The Royal Scottish Academy has certainly accomplished well its mission in encouraging the study and practice of the art of painting. The great amount of mediocre excellence appearing on its walls is itself a great result, creating a want and providing the supply. Signal as has been the success of the Academy in respect of painting, as indicated by the crowd of applicants for space and the number disappointed, small praise is due to it for its encouragement of architecture, as a sister art, entrusted to its fostering care. It has not given a fair field or any favour to the production of original design, or any encouragement to induce exhibition of works which would make the annual exposition really representative of what is interesting and important in the architecture of Scotland. Architecture is treated as an interloper, hardly fit to bear other pictures company, having no local habitat of its own. Many of the drawings are lost in the crowd of water-colours, and others placed with supreme and ignorant indifference to the character of the design or the scale of its artistic draughtsmanship. An etching, or geometric elevation, with much fine detail in the drawing, such as 937, Mr. Aspen's "Yarmouth Town Hall," or 959, Mr. Sheill's "Church Front at Dalkeith," is sent beyond reach of human optics to command the character of the detail, and small scale drawings have been perched aloft to complete the pyramidal outline of the group below. Another subject, drawn to a scale preposterously large for its importance, is placed close to the spectator. In short, the arrangement of architectural drawings, as distinct from the water-colours, seems to indicate that they are, with few exceptions, considered as the pieces of a Chinese puzzle, to be fitted as best they can into any space left for their reception after the water-colours have been served. In the face of treatment such as this, it is not encouraging to prepare important works for exhibition. Even ordinary subjects, which necessarily bulk largely in the Exhibition, would probably appear in fewer numbers, were it not that building committees and proprietors are supposed to desire a sight of their edifices on the walls of the Academy.

The architectural section this year is a good one. There is less of faulty delineation and commonplace design, a result, no doubt, owing to the fact that the number of subjects is very much less than in former years. The circumstance has also occasioned a better arrangement of the architecture which occupies one compartment to itself—the side selected for it being, of course, the worst.

The most important work delineated is the Royal Infirmary. It is a bird's-eye view of this great national undertaking, coloured in monochrome, and presents a very clear view of the vast extent and order of arrangement of the several departments. The drawing is not executed, of course, to a very large scale, and its ridiculous position next the ceiling, requiring the spectator to look up at it when he should be looking down, is very aggravating to the eye. 974, "Interior of Library of Royal College of Surgeons," should have been hung where the Infirmary is placed. It is unfortunate in colouring, and lacks precision of outline, so necessary to perspective, of its various distances between the book-cases. 973, "The New Hospital for Incurables," is Classic, of simple, dignified proportions. Exception may be taken to the small pediment which ornaments the centre, and which looks poor for lack of company. Mansion

houses and street architecture are few and feebly represented. 970, "South-east View of Kenwith, Perthshire," is a weak etching, and it is to be hoped that the north-west view is more inviting, with less of the donjon-keep about it. 957 is a piece of street architecture in Paisley, comprising the offices of no fewer than three branch banks. The design shows nothing of the ornamental other than what is provided by a judicious arrangement of the features peculiar to the Scottish Baronial style in its plainer character.

The strong point of this Exhibition is church architecture, of which there are eight or nine separate subjects, with the novelty of several drawings illustrative of some of the designs. Mr. R. Anderson, who is a member of the Academy, sets a good example in giving exterior and interior views, fully illustrative of his designs. These drawings are executed to a reasonable scale, and may be considered models of architectural delineation, as pen-and-ink sketches. 940, "Episcopal Church at Forfar," has the ordinary nave, aisles, and small tower and spire. The chancel is large, and well-lighted, but the triplet at the east is disfigured by two very awkwardly-placed trefoil piercings. The pillars of the nave have only imposts, and the whole design appears to be of an economical description. 965, "The New Free Church at Kirkecaldy," by the same architect, is interesting as an attempt to dress out the old-fashioned Presbyterian meeting-house, with its circumambient galleries, in Early English Gothic. There are, however, novelties in the construction. The plan is evidently of great width in proportion to the length, and the front shows a large, circular sweep, with the tower and spire at its side. The roof is partly carried on iron pillars, boarded over at the tie-beam. A wooden clerestory, lighted with borrowed lights from skylights in the lower portion of the slating, with the bracketed supports, has a good effect. But the result is not by any means a very successful attempt at solving the problem, which seems to be insoluble. The proportions of the plan are at perpetual war with the structural conditions to which Early Pointed Gothic owes its origin. The spire, which is very plain, but well-proportioned, looks lanky beside the breadth and rotundity of the church, and enhances the incongruity between the proportions of the edifice and its Gothic detail.

964, "House at Colinton," by Mr. Anderson, is a very faithful reproduction, externally, of the domestic architecture of the fourteenth century, but will hardly satisfy the conditions of the "picturesque" or "pretty," popular in the nineteenth.

Another church, exhibiting some novelty in its design, is 953, "A New Parish Church at Galashiels." This is also an attempt in another direction, to solve the difficulty of reconciling Gothic proportions and detail with the comfortable accommodation of a large congregation. Galleries in this case are dispensed with, and ground-floor space is attained by adding to the nave, by aisle and transept projections. The peculiarity of the design consists in the equal apportionment of aisle and transept as additions to the nave. The tower is placed next the transept. The drawing of this and some others is executed to a scale disagreeably large for artistic effect, and is very indifferently done, and inaccurate in its perspective of detail. There is no view of the front or the interior, and the aspect represented depends for its effect on the three gables of the transept, with the three large Geometric windows, somewhat mystically balanced by the three smaller lights of the aisle and three corresponding lights of the clerestory above. The tower and spire, like most of the towers and spires exhibited, is a curiosity. It presents the striking novelty of a smaller tower peeping above the battlements of the one below; each with its cornices and crocketed finials, of which the one at the west corner seems very insecure. The same characteristic as to the exaggerated scale applies to 960, "A New Church at Portobello"; and another feature conspicuous in both is the amount of louvre-boarding and the double bell chambers, one over the other, leading to the inference that an unusual number of bells have had to be provided for.

938, "A U. P. Church in Dundee" is a water-colour sketch of a design in the Norman or Romanesque, and comprises nave and transepts, with the inevitable tower and spire at the corner. The detail of the large west window is not very

happy, with its transept and supports and semi-circular wheel above. The tower shows a preposterous amount of monster louvres, which very much impairs its appearance of stability.

945 is a drawing, or rather three rough sketches, in monochrome of "Anderson Free Church," Glasgow; two exteriors and one interior. The site appears to be the brink of a very steep declivity, and, as a whole, the composition is picturesque. The design is ordinary Early English; and galleries appear to run round the interior, which shows an aisle beyond the nave. The effect of the gallery cutting through the piers is not happy. One peculiarity of the design which strikes the eye is the shortening of the lights over the pulpit, in order to provide a large wall space for some pictorial illustration, which is dimly indicated in the sketch, and for which, it is to be feared, a faculty will be difficult to get from the General Assembly.

952. "A Competition Design" is a pretty water-colour sketch of a church and its adjoining hall. The detail shows a very elementary acquaintance with Gothic detail; but the proportions appear to be good and the several parts are pleasantly grouped.

967 is a design for organ case and pulpit in Decorated Gothic. Both are very ornamental. The latter is a rostrum, rather long for its distance from the wall, with triple canopy overhead. The supports of the canopy are too slender, and the two brick pillars carrying the slightly projecting part of the front are Norman in their proportions.

There are many excellent water-colours representing architecture and the picturesque in bits of Melrose, Roslin, and St. Monance Churches. Mr. Arthur's picture of "Lucy Ashton's Chapel" is very accurately drawn, and the landscape and light of the picture are finely rendered. E. George's works are always welcome, and in 903, "The Cathedral and Castle of Linburg," he has produced a picture which exhibits a rare combination of the picturesque in nature and art, and illustrates forcibly the character of the age which made the lords of the manor select such rocks for a foundation. Mr. Lessels sends a large and expressive water-colour view of the interior of St. Jacques, Antwerp; but the arches of the nave, by some mishap, are not in the same plane as the clerestory above.

NEW R. C. CHURCH IN CADOGAN-STREET.

A FEW weeks ago we referred to a new church in the neighbourhood of Cadogan-square from the designs of Mr. J. F. Bentley, upon which we commented in favourable terms. Last Saturday the Architectural Association visited the edifice, and we take the opportunity of giving our readers a general description of the interior. It is not exaggeration to say that this church, though unpretending in its external architecture, is a building displaying a more than ordinary degree of merit, and marks a development of Gothic that has unfortunately found but few able exponents. Mr. Bentley, like Mr. Pearson, is a thorough master of the true spirit of Gothic detail, and it is this peculiarity which above all else claims our admiration when we enter the church in Cadogan-street. One of the greatest weaknesses of our church architects has been the multiplication of detail and a tendency to efforescence. In Mr. Bentley's church we are impressed by a sense of supreme simplicity and breadth. There is nothing fussy and fidgety about the arading, the clerestory, or the roof. Most modern churches are spotted or striated in coloured material; in this building there is nothing of the sort. There is no attempt at brick relief, all is of a quiet warm stone tint, with plenty of wall surface for frescoes as means permit. Corham Down stone has been chiefly used in the interior, and the chancel is completely faced with ashlar of this material, while externally white-stocks with stone dressings have been used. The roof is devoid of all cumbersome and elaborate framing; a plain wooden barrel vault of crown tint, slightly pointed, relieved by moulded ribs (or principals) and rafters painted of a bluish green, covers the nave, while the chancel roof is varied by being composed of a series of eaves, the springing ones being stilted. At each principal is a simple tie-beam suspended in the centre by an iron king; the principal ribs are framed above and below the tie-beam, which

latter intersects the ribs above the springing. In the aisle roofs we observe a series of three eaves similarly treated, the lower one being deepest. The plan of church comprises a nave of four bays, 82ft. long and 27ft. wide; a chancel, 35ft. in length by 24ft. in width; aisles 15ft. wide each, and transepts bounded by the outer walls. At the east end of north aisle there is a Lady chapel, on the south of chancel a chantry, with an organ chamber, and a sacristy projecting beyond. The height to ridge of nave inside is 55ft., that of chancel being 52ft. The proportions are effective, and we are informed the acoustical qualities are good. At the north-west corner is a spacious porch, which forms the westernmost bay of aisle, and we notice its eastern wall is pierced by a four-light window, through which a pleasing vista is obtained of the aisle, and the east Geometric window of Lady chapel. Opposite the porch, forming a gabled projection, is the baptistery, while above the former is a tribune approached by a spiral stair, which is externalised as a low roofed turret flanking the west gable. One pleasing variation upon the usual plan is the internal buttressing in the north aisle. The site was cramped, and as this side of the church is bounded by Cadogan-street, the architect has wisely utilised the space that would otherwise have been taken up by outer buttresses, making the wall flush externally. By this means, a series of recessed bays are produced in the aisle, arched over by drop arches, and one of them is converted into three confessionals with arched heads, the treatment of which is very effective. Another feature adding much to the east end is the screened triforium formed on the inside of the east window above the altar, access to which is obtained by a small turret at the north-east angle eastern gable. The passage or gallery is formed within the thickness of the wall, the inner face being relieved by a beautiful open screen, forming four cusped lights under three arches with traceried heads. Below the open screen and above reredos runs an arading of cusped panels, which also continues round the sanctuary sides. Below this the altar end will have a carved stone traceried reredos of curvilinear style though without colour, and the sides of reredos and return walls of sacristy are enriched by a series of gabled panels, the heads of which are crocketed and their intersections carved with angels by Mr. McCarthy, to whose work we must award high praise for the true Gothic feeling he has imparted to it. The band of carved leafage over the reredos and the heads at the termination of labels in sanctuary are particularly fine in expression, while the foliage of caps and pendant shafts supporting ribs of roof are close, and devoid of that bunched and coarse effect we generally notice in churches. The nave is effective in its simple division. The clerestory is lofty, and pierced with cusped lancets under drop arches, two to each bay, while that of the chancel forms a series of lancet lights. The arches of nave are moulded with exceedingly effective members, the chief of which is a bold ogee, finishing at the lower angles with a roll member, slightly pointed. The pillars are on plan elongated octagons, a slightly pointed shaft running up the narrow side of each on the nave side carrying the main principals. In the chancel they are varied, and have a rather peculiar section with deep hollows. The interior dignity of the church is enhanced by the four lofty lancets of equal height internally, which pierce the west gable end. This window has drop arches resting on small detached shafts, 21 feet high, of Hopton Wood stone, tied at intervals into the jambs by iron bars. The centre pillar at the east window screen is also of Hopton Wood stone. Another pleasing detail is the treatment of the entrances at the west end, the thickness of wall being here reduced internally by three drop arches. We note a great variety and much refinement in the detail. The organ chamber, for instance, has an open Late Curvilinear or Flamboyant screen in front of the organ; the Lady Chapel, east end, has a Geometric window; the reredos tracery is certainly Late, while the remaining portions are evidently Early in character. The cap mouldings are fine and close set, and, on the whole, the masonry is highly creditable. Mr. Howell has acted as foreman of masons, under the contractors, Messrs. Braid and Sons. The flooring will be of boards under the seats, and tiles in the passages, chancel, and chapels. The windows are filled with plain cathedral glass set in lead square panes. Externally, the simple lofty lancets at the east and west ends are enclosed

under arches, and have small stone ashlar buttresses on the broader faces or mullions. The masses of main gables, transepts, and aisles, together with the angle turrets (the western one being only temporarily roofed with a low tile roof) group very agreeably, and the colours of bricks and tile harmonise together. The execution of the works reflect much credit on the contractors, Messrs. Braid, and upon the able clerk of works, Mr. Thomas Spooner, who has acted under the architect. The carving has been entirely entrusted to Mr. McCarthy.

ROYAL ACADEMY LECTURES ON ARCHITECTURE.

ITALIAN GOTHIC THE PRECURSOR OF THE RENAISSANCE.

IN commencing his second lecture Professor E. M. Barry said he should devote this course to a consideration of the Renaissance in Italy, and as a prelude to so doing, should speak that evening of Italian Gothic as the precursor of the Renaissance. That change of style must be roughly divided into three periods, the Transitional, the Roman, and the Pedantic schools. At the first signs of the Renaissance in Italy, Gothic was beginning to exhibit symptoms of decadence, both in general forms and in detail. Vigour of thought was replaced by refinement of execution, and architectural ornament had become uninteresting. The Italians had always worked on somewhat different principles from the architects of sterner climes. Living upon classical soil, and among the dry bones of old Classic art, they were in the most favourable position for welcoming a change which to them seemed but a natural return to ancient traditions. Among the peculiarities of the Italian Gothic was a spirit of horizontalism opposed to the all-pervading verticality of our own Mediaeval architecture. In the larger diameter of shafts, and their frequent use as single supports, reminiscences of the columns of Greece or Rome suggest themselves. The pointed arch, moreover, seemed unable to hold its own. The Italians loved the round arch, while they only tolerated the pointed form. Ignoring buttresses, they tied their arches together with iron rods, and seemed incapable of those daring feats of construction familiar to Gothic architects elsewhere. Repose and breadth of effect had more charms for the Italian mind than the bold projections, deep shadows, mysterious intricacy, and complicated details of Northern work. They had broken, indeed, with the simple lintel construction of Greece; but the arches of Rome were less easily forgotten, and their employment less readily renounced. The graceful campanile of Giotto, at Florence, illustrates many of these peculiarities, and others are exemplified in the cathedral to which it serves at once as a foil and as an appendage. This great church of Ste. Maria dei Fiori, the Duomo of Florence, stands forth as a giant, disdaining ornament or smallness of detail. Its features are few, simple, and almost colossal in scale. In it we see a remarkable plainness and simplicity of plan. It was commenced by Arnolfo di Lapo, just before his death, which occurred about 1300. He is usually credited with the general conception, arrangement of plan, and construction or design of vaulting, always excepting the dome, added long afterwards by Brunelleschi. With this, the largest Mediaeval church in Italy, may be advantageously contrasted Westminster Abbey. In the nave of the former, 250ft. long, there are but four arches; in the latter example, we find twelve arches in a length of 233ft. Each church is divided transversely into nave and aisles, but these three divisions occupy a space of 125ft. in the Italian, and only 75ft. in the English example. At Florence, we find a grand central space surmounted by a pointed dome, with three tribunes, all alike covered with semi-domes. At Westminster, there is a multiplicity and intricacy of parts, planned with various angles, and much diversity of dimensions and detail. At Florence the scale is too colossal to please, and has the character of a small design unduly magnified. On entering the nave, the great arches, although well and gracefully proportioned, have a bare and unsatisfactory effect, and on passing to the central area, under the dome, this feeling is intensified. The grand dimensions of the dome, 137ft. diameter, and about 286ft. high, are thrown away, by reason of the paucity of detailed parts of moderate

size, to serve as a scale for the whole. Arnolfo's nave is groined in a simple manner, and, like many other parts of an Italian Gothic building, the vaulting seems incomplete without painting. The designers of these structures regarded them rather as a framework, to be filled in by others, than as works of architecture, complete in themselves. Simple forms, spaciousness, and great wall-spaces are consequently found associated with Gothic architecture in Italy. The Northern architects had a less wealth of art, but more skill and self-reliance; they were engineers as well as artists, and, employing buttresses in the most scientific constructional forms, they were ever advancing in their art. The Italians shunned buttresses. Strength was usually obtained, less scientifically, by an enormous thickness of wall, and resort was had to iron ties to keep the arches from thrusting out the walls. With their love for repose and breadth of effect, they preferred a plain wall, as at Florence, to the varied surface, as at Westminster, with its variety of light and shade, and its picturesque outline, both of plan and elevation. They did not, indeed, wish their walls to be undecorated. They were ready to cover them with marbles, arranged in panels, and to crown them with cornices of great elaboration. Such marble veneering is essentially weak ornamentation; it indicates no construction, and might have been applied by any one, and at any time. It serves to give some scale to the building; but it is an independent attempt at decoration, and not an architectural design successfully achieved. Italian Gothic must, indeed, be regarded as an incomplete style, not fully worked out. Whether we regard the general principles of composition, or the detailed forms adopted in Italy, we come everywhere upon traces of Classicism, which seemed to herald the Renaissance. Amongst the details of this and other Italian churches recalling the Classic forms we find single shafts used not only in arcades, but as mullions for windows, and in these cases often doubled on plan with happy effect; the abacus and lowest member of base are nearly always square, and there is occasionally a diminution in diameter from base to capital. The archivolts are frequently plain with square edges. When the arch was not actually square in section, a few indentations, with the occasional interposition of large beads, filled the place of the smaller beads, fillets, chamfers, and hollows, of English Gothic. The cornices, again, formed strong horizontal lines round a building. In their fondness of plain surfaces, and dislike to bold projections, the Italian architects may be said to have designed their buildings as elevations, while our own medieval architects thought theirs out in perspective. The brilliant climate had something to do with these differences, and another reason was the fondness for applying thin veneers of costly marbles to the whole external and internal surfaces. In spite of all care, it has been impossible to prevent these slabs from cracking, or bulging, as unforeseen pressure comes upon them; and then all sense of permanent security and enjoyment vanishes. The introduction of marble in panels, recesses, or spandrels is not liable to this objection. The panelling on the outside of the cathedral at Florence recalls the work of the cabinet-maker rather than that of the architect. That building is however, incomplete, and if the entrance-front had been finished, as designed by the architect, the whole effect of the exterior would have been more pleasing. We do not, indeed, know how Arnolfo would have treated his façade, but in Siena Cathedral an example exists, very rare in Italy, of a front entirely finished. In this case, we have an elevation of great richness and much beauty of detail. It is, however, an application to the building, a veneer on a large scale, for the outline bears but an imperfect reference to the constructional form of the building within. Gables appear for ornament, without roofs behind them, and the aims of the designer were akin to those of the scenic artist, who presents us with a frontispiece, and does not allow us to turn the corner, or view it save from one point. The interior of Siena Cathedral is one of the most charming of Italian Gothic churches, not so much for its architecture as for the exceeding beauty of detail of the accessories thereto. The strongly-marked banding of various coloured marbles in its walls is, indeed, monotonous, and inharmonious with the vertical principles of Pointed architecture, but

the whole interior glows with gorgeous colour. We have exquisite carvings, elaborately inlaid woodwork, paving of splendid design and execution, bronze and ironwork, gilding and coloured marbles in profusion. The architect has provided an arena, within which art revels. The details are everything, and the general architectural idea is smothered by those who should have been its servants. In further comparing Italian with Northern Gothic, we cannot but notice the difference in the windows, not only as regards their relative frequency and size, but also their architectural character. In the great Northern churches the architects delighted in large and elaborate windows. In Italy they were few and far between. The brightness of the sunny South taught its builders to exclude light and glare, and the use of coloured glass was not encouraged. Stained glass would have been inconsistent with the methods of internal decoration common in Italy, for Italian architects applied to their walls that which their Northern contemporaries placed in their windows. There is very little tracery, and where it exists it seems designed to exclude the light, while the absence of an adequate clerestory causes a heaviness, lack of gradation in height, and want of variety. Of late years, so much attention has been given to Italian Gothic architecture that many of our architects have adopted details from it into their own designs. The lecturer saw no grounds for condemning such a practice, apart from the special circumstances of each case. But to utilise these details well and reasonably is a matter of no small difficulty. The essential quality of all true art is its fitness, and in adopting Southern detail into Northern work, the presumption is against the process. We should, therefore, be very sure that in attempting fusion we are not sacrificing principles, or offending common-sense. With this proviso, the lessons of Italian Gothic are before us, and may, in certain cases, be followed with advantage. One inducement to adopt the architectural details of North Italy has arisen in consequence of our habitual employment of brickwork, both on the grounds of economy and the difficulty of procuring stone. Brick has, of necessity, become the common building material, and a style of architecture which seems to lend itself readily to its use has obvious claims on attention. In the plain jambs, simple mouldings, geometrically enriched cornices, and string courses of North Italy, we have features specially appropriate to brick architecture, while by the use of the column the use of numerous small pieces in the mullions of the windows is avoided, a very apparent defect in the brick Gothic architecture of Northern Europe. The adoption of terra-cotta, again, has proved an argument in favour of Italian types. The use of this material is splendidly exemplified in such Italian buildings as the great Hospital at Milan. In England, apart from a few exceptional instances, terra-cotta has held an inferior place, but it offers great opportunities to the architect of taste and judgement. The limits within which terra-cotta can be properly applied may be broadly defined as ornamental rather than constructional. In using brick in our large towns, we must bear in mind the changes of our climate, and the consequent dinginess which, sooner or later, settles on brickwork, and obliterates distinctions of colour. We are often very hard on our immediate predecessors who covered their brickwork with stucco; but their buildings, at any rate, admit of being cleaned, so as to afford some cheerfulness to our streets. Architects have, perhaps, been too indiscriminate in their denunciations of plaster. For interiors, it has many advantages, and is often to be preferred to the rude brickwork, not too good, either in quality or workmanship, which we are asked to accept in exchange. No one would use cement dressings and cornices if he could do better, but for coating plain walls plaster will act as a protecting covering, giving both warmth and dryness. There should be some place in our work for methods of building which possess these advantages, and the question arises when and now plaster may be legitimately used. The Italian Gothic architects had not much affection for brick surfaces in themselves, being always ready to cover their walls with veneers of marble, an application of a covering more foreign to the structure treated than cement or plaster. It is impossible to lay down absolute rules in such matters. Architecture should satisfy the reason, and should please the taste; and all the arguments in the world will not make a man like

that which his soul abhors. In studying the art of other times and nations, let us not forget the dictates of common sense, or the needs of our own age and country.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

THE BRITISH ARCHÆOLOGICAL SOCIETY.—Some interest was created at the meeting of the British Archæological Society on Wednesday week by the exhibition of a number of small objects in jet and jet-like substances, with bone hair-pins, &c., said to have been found at South Shields on the site of the recently-discovered Roman station known as "The Lawes," and about which much curiosity has been excited among the antiquaries of that town. The majority of these objects, chiefly from the "finds" of other persons who are continually at work on the spot, must be regarded with considerable suspicion as being manufactured on purpose to mislead and entrap the unwary, and the chairman, Mr. H. Syer-Cuming, in perfect accord with most of the members present, denounced them as "impudent forgeries." Mr. Loftus Brock, F.S.A., followed with a description of a recent discovery at Carlisle, on the course of the Roman wall, of a large monumental stone slab, beautifully sculptured, and representing a female figure seated beneath an architectural canopy, holding in her right hand a round fan, like those used by ladies of the present day. A child stands by her side, and on the canopy are the figures of two lions devouring human heads. Mr. Brock alluded to this sepulchral monument as being similar in artistic treatment to the famous Palmyrene tombstone, found last autumn at South Shields, as the photograph of it clearly showed, and closed his remarks upon the interesting memorial by pronouncing it undoubtedly Roman, though without any inscription remaining. A descriptive paper, by Sir Lewis Jarvis, V.P., on "Middleton Towers," now by his skillful architectural management restored to something of its former baronial character, having been built by Lord Scrope, temp. Edward III., then followed; with a short paper by Dr. Harker on "Pre-historic Remains found at Morecambe," read by Mr. De Gray Birch, and one by Mr. Syer-Cuming, on beggars.

CHIPS.

The Rev. F. Storer Clark, vicar of St. Peter's, Greenwich, complains that he is one of several clergy who find their ministry marred through an echoing church. "If any brethren have been able to remedy such a calamity, we shall be thankful to know of the remedy, or of any architect who has made this a special study."

The Ramsgate Town Council decided last week to convert the old fish market into borough surveyor's offices.

The Cork Town Council on Monday elected Mr. M. T. O'Keefe, of that city, as city engineer and surveyor. The salary is £350 per annum, and the surveyor is to give his entire and exclusive time to his official duties.

The Dorking Rural Sanitary Authority have been served with a writ under the Rivers Pollution Prevention Act, on account of the alleged continued pollution of the Pibrook by sewage. In consequence of this, negotiations have been accelerated for the formation of Dorking and Leatherhead, which latter is at present in Epsom rural district, into a combined district for sewerage purposes.

A permanent contagious diseases hospital is about to be built at Tunbridge, from the designs of Mr. Noot.

An inquiry was held at South Petherton last week, before Major Tulloch, in reference to an application from the Yeovil Rural Sanitary Authority for sanction to contract a loan for the drainage of South Petherton. The sewage will be utilised on farm land.

The Wolverhampton School Board are about to enlarge the infant-schools in Redcross-street, at a cost of £630. Mr. Fleming is the architect.

An inquiry was recently held at Petworth, before Mr. Arnold Taylor, an inspector of the Local Government Board, with reference to an application from the Rural Sanitary Authority of Petworth for approval of a special drainage district comprising a portion of the town of Petworth, and for sanction to borrow £2,500 for works of sewerage for the said district. No opposition was shown towards the scheme.

A stone spire is being added to St. Peter's Church, Bournemouth. The work will cost £3,000, and will be completed by Michaelmas.

THE NEW NATURAL HISTORY MUSEUM—NATIONAL PROVINCIAL BANK AT SUNDERLAND—"BUILDING NEWS CLUB" DESIGN FOR A WAYSIDE INN—THE LOGIC OF ARCHITECTURE—HOUSE OF THE SEVENTEENTH CENTURY AT DERBY.

OUR LITHOGRAPHIC ILLUSTRATIONS

NEW NATURAL HISTORY MUSEUM, SOUTH KENSINGTON.

At last we are enabled to publish the promised general view and principal plan of this important building, of which we have already given a large series of working drawings showing the terracotta construction and ornamentation (see *Building News*, Oct. 11 and 25; Nov. 8, 22, and 29; and Dec. 13 and 20, 1878). The plan which we give shows the building as executed, and it will be noted that the large hall formerly called the "Index Museum" is to be known as the "Typical Museum." Our perspective view is the same as was exhibited at the Paris Exhibition last year. The building will very shortly be completed, though probably will not be occupied during the present year. Mr. Alfred Waterhouse, A.R.A., is the architect.

NATIONAL PROVINCIAL BANK OF ENGLAND, SUNDERLAND.

Our view of this building, which is one of the important branches of the above banking corporation, is taken from a drawing exhibited in the Paris Exhibition of last year. The fronts are of Portland stone, and the site being a corner one in the High-street, leading from the Docks to the railway-station, the position is commanding. The entrance at the angle is through a handsomely panelled mahogany lobby, into the banking-room, which is a lofty room 40ft. square. The walls and ceilings are divided into bays, panelled and moulded; the counter and desk fittings are finished in mahogany; the public space is laid with encaustic tiles, and the artificial heating is by means of hot-water piping and coils. In the rear are the manager's consulting and strong rooms; additional spacious safe-accommodation is provided in the basement, all fitted in the most approved manner. The remainder of the latter story is devoted to clerks' luncheon-room, lavatory, and conveniences. The upper stories give comfortable accommodation to the bank's residents, which are approached from both streets. The works were carried out by Messrs. Shafte and Barry, of York, from the designs and under the superintendence of Mr. John Gibson, of Westminster.

A WAYSIDE INN.

PERHAPS no subject has taken so much with the members of our Designing Club since we commenced the second series as the one for which we give the selected design to-day; at any rate, the contributions were not only more numerous than usual, but the character of the foremost of them was very nearly of equal merit. We have already remarked upon the several plans, leaving little to be said here. The selected design is by "Motto J.," whose drawings herewith will explain themselves. We shall publish the design by "Mechlin," which was awarded the second place.

THE LOGIC OF ARCHITECTURAL DESIGN.

For a description of these sketches see our report of Mr. H. H. Statham's lecture on p. 185, and also last week's number, p. 159.

OLD HOUSE IN DERBY

This house is in the Wardwick, opposite the new free library, from an upper floor of which the drawing was made. It had formerly a greater frontage to the main street, having a third bay, but when the Cross-street was made or widened the gable and bay were taken down and rebuilt on the flank. It was erected in the first half of the seventeenth century. The way in which the supporting wall is cut away by the opening is worthy of remark.—WM. RD. LETHABY.

THE ENGINEERING OF WATER SUPPLY.

THE water supply of our large inland towns is a matter of such moment that any information bearing upon the question has a more than usual interest. Two papers on the supply of water in Australia were read and discussed on Tuesday week at the Institution of Civil Engineers. One paper dealt with the Geelong water supply at Victoria, and was read by Mr. Edward Dobson, Assoc. Inst. C. E. It appears that in 1871 Lieutenant-Colonel Sankey, R.E., reported to the Victorian Government, recommending the construction of certain works, namely—an open channel from Wallace's Swamp to the Stony Creek reservoir; a storage reservoir at the head of the creek, 26 miles from Geelong, with a capacity of 754,000,000 gallons; a brick-lined aqueduct, communicating by a natural water-course with a small pipe head reservoir at Anakie Gap, holding 1,330,000 gallons; a 13½ mile length of 12-inch and 14-inch main, leading from the pipe-head reservoir to the service reservoir; a service reservoir, to hold 6,000,000 gallons; filter beds; several miles of mains, including 42 miles of sub-mains, varying from 12 inches to 3 inches in diameter. Geelong has a population of under 25,000, including the suburbs, and Colonel Sankey's plans contained provisions of some interest. One of these was that the water should not be allowed to rise within 15 feet of the by-wash until all subsidence of the dam had ceased; another, that relieving reservoirs should be constructed to lessen the pressure on main between the pipe-head and the service reservoir, and that there should be a by-pass at the service reservoir to allow of its being shut off for repairs without interfering with the town supply. Mr. E. Dobson, as resident engineer, carried out these works, and his paper furnishes some useful information respecting the failure and repair of the Upper Stony Creek reservoir. He attributes its failure to an injudicious selection of site, or rather foundation, a frequent cause of similar casualties. The puddle wall had subsided, and the face of dam slipped in consequence. In repairing the dam the water and slush were pumped out below the outlet, a new by-wash was cut 17 feet lower than the original, and the stone from the cutting was used to fill up the slip, while the slope of the bank was made 4 to 1 instead of 3 to 1. Describing the lower reservoir dam, Mr. Dobson says it is of concrete, erected in a gap at the lowest of the reefs which divide the valley into basins. It stores 142,000,000 gallons, and has 42 feet depth of water over the outlet pipe. The foundation of dam rests on vertical strata of slate and limestone. In the composition of the concrete the following materials were used; broken sandstone and cement mortar, made of pit sand and Portland cement, in the proportions of 2-inch metal, 4½; screenings, 1½; sand, 1½; cement 1. Short tunnels had to be driven through spurs in the gorge of the Stony Creek, consisting of vertical strata of limestone and slate. Their size was about 6 feet by 3 feet, and the cost a little more than £3 per lineal yard. Both lithofracteur and ordinary blasting powder were used. In the work of pipe laying an immense amount of labour in crossing creeks and weirs, boring and retaining walls, was undertaken, and as a regular gradient could not be obtained, the bottom of valley was followed to the mouth of the gorge, then the spurs were tunnelled through, and it ascended by a steep incline, so as to obtain the shortest route to the tunnel's mouth, without rising above the gradient. This was fixed at 4 inches per chain for the 9-inch pipes, and at 2 inches per chain for the old 14-inch pipes. They had to deliver

720,000 gallons every twenty-four hours. Blow-off cocks were attached to the mains at the principal summits. The average cost of laying was less than 11s. per yard; this included cartage of pipes, 24 miles, retaining walls, &c., but was exclusive of cost of tunnels and cost of pipes. We have no space to enter into other details. The second paper, on the "Sandhurst Water Supply, Victoria, Australia," by Mr. Joseph Brady, M.I.C.E., dealt with the construction of storage reservoirs and filter beds he had designed for the purpose of the extension of the water works. Sandhurst, we may remind our readers, is the central town of the Bendigo gold field, and is about 105 miles north-west of Melbourne. The population was 35,000; the average rainfall for 13 years was 23.13 inches, and the city is of considerable elevation. Before the year 1858, Sandhurst was supplied by rainwater stored in small iron tanks above ground. With regard to the details of the reservoirs given by Mr. Brady, the surface level at Big Hill reservoir was 991 feet above sea level. Its area was 18 acres, and gathering ground nearly 4,000 acres. The formation was schistose. The dam was of earthwork, with a centre puddle wall, 350 yards long, 30 feet high in centre, and abutted on abrupt hills at the ends. Its cost was 1s. 7½d. per cube yard, and of the puddle, 4s. 9½d., and it contained 77,000 cubic yards of material. The top width was 12 feet at 5 feet above the highest water level, the slopes being 3 to 1 inside covered with gravel and 2 to 1 outside soiled and grassed. There was a by-wash for surplus water, which discharged into a valley, and the outlet was by a 7-inch east-iron pipe, well protected, and fitted with a brass delivery valve, of Guest and Chrimess pattern. The Crusoe reservoir had a capacity of 330,000,000 gallons; its area was 80 acres; and its greatest depth, 40 feet. The dam, of earthwork, is 700 yards long, 12 feet wide at top, and 47 feet high; its cost was £25,400. The slopes are 3 to 1 inside, and 2 to 1 outside, the former covered with rough stone pitching and gravel, and the latter grassed. Provision was made for shrinkage. The by-wash was obtained in a depression of the hills, the surplus water discharging into a lateral valley clear of works. The outlet was a cast-iron siphon, 18 inches diameter, and 515½ feet long, the inner leg being 206½ feet long, the crown, 88 feet, and the outer leg, 221 feet. This siphon did not cross the dam at right angles to a vertical plane, but was laid on its side. It finished with a bell-mouthed end in the lime-pond of the settling works, under a constant head of 4 feet of water. At a level of over 800 feet, the discharge of water was 4,500 gallons per minute. The filter beds were described, but we need not refer to these, beyond saying that the lime process was used, and the maximum daily supply delivered was 200,000 gallons. The wages were high, bricklayers being paid at the rate of 12s. per day, and labourers at 8s.

THE collection of maps, plans, and views of London and Westminster, made by the late Mr. Frederick Craze, and lent to the South Kensington Museum by his son, Mr. J. G. Craze, which we have already noticed, is now on view from 10 to 4 daily in two of the upper rooms in the galleries on the west side of the Horticultural Gardens. The plans and views selected from the collection for exhibition are 3,085 in number. A complete catalogue, compiled from Mr. Craze's larger work, has been issued, and may be purchased in the Museum.

A Local Government Board investigation was held at Redhill, on Saturday afternoon, with reference to the quality of the water supply by the Caterham Spring Water Company. A handbill, entitled "Typhus Fever," has since been circulated in the town. It states that it has been represented to the Mayor that the Caterham water has been accidentally contaminated so as to render it at present unsafe for domestic purposes, and persons are cautioned against its use for drinking or cooking.

The Waterford Harbour Board having obtained from the Treasury the promise of an advance of £40,000, in such sums as may be required, for the construction of a dry dock, will proceed with the works forthwith.

A new organ was opened at Brentwood Congregational chapel on Sunday week. It was built by Messrs. Hill and Sons, of Camden Town, at a cost of £380. The choir-chamber before the organ and situate behind the pulpit has been rearranged and other structural alterations carried out by Messrs. Winter Brothers, builders, of Brentwood.

MAXIMS OF ARCHITECTURAL MORALITY. I.

Architecture being based on practical requirements can only be true and logical so far as it is in accordance with and expresses the real needs of the community.

II.

The plan of the building is the basis of the whole design. A good plan is one in which the various departments are arranged and combined in such a manner as to ensure the greatest convenience and the best possible effect.

III.

The exterior grouping and design of a building should arise out of and indicate the interior plan and arrangement.

IV.

The architectural design (both internal & external) should arise out of and express the scientific construction or the "plastic" of the building.

Ornament must be so introduced as either to emphasize the construction or to be manifestly independent thereof and must be designed with reference to the material in which it is to be executed and the climate under which it is to be seen.

V.

No feature not arising out of the plan or construction can be added to the architectural design of a building under the pretext that it is "ornamental." Such a feature is an architectural falsehood.

NOTES ON ST. PAUL'S CATHEDRAL.*

(Concluded from p. 133.)

The *prima facie* points which make against the Oxford plan No. 1 of the Old and New Cathedrals of St. Paul, are—firstly, that it does not fit our new discoveries; secondly, that the internal detail is drawn in an obviously careless manner, the pillars of the central tower alone seeming to have been properly laid down, and the rest merely sketched in hap-hazard; and, lastly, the curiously oblique lines of the fronts and ends, &c., already noticed. The last-mentioned *prima facie* doubtful point is, however, really an evidence of the accuracy of the plan. The second is nothing more than inattention to a detail which had nothing to do with the gist of the drawing, and the first-named misfit has arisen from the fact that the draughtsman was put out by an irregularity of which he had no previous experience, namely, a deflection of the axis of the choir from that of the nave. This appears to be the solution of the whole difficulty, and when the drawing is corrected for this peculiar arrangement everything fits in its place, and the oblique lines are all of them reduced to their proper square directions. And now the plan becomes intelligible, but I have additional evidence, and will here quote a passage from the "Parentalia."—"The reasons for changing the site of the Church and taking up all the old foundations are chiefly these:—First, the Act of Parliament for rebuilding the City had enacted that all the high streets (of which that which led round the South side of St. Paul's was one) should be 40 feet broad, but the old foundations straitened the street towards the East end to under 30 feet. Secondly, the Churchyard on the North side was wide, and afforded room that way to give the new Fabrick a more free and graceful aspect. Thirdly, to have built on the old foundations must have confined the Surveyor too much to the old plan and form: the ruinous walls in no part were to be trusted again, nor would the old and new work unite or stand together without cracks. It being found expedient therefore to change the foundations, he took the advantage of more room Northward, and laid the middle line of the new work more declining to the North-East than it was before, which was not due East and West, neither did the old front of the Cathedral lie direct from Ludgate, as it does not at present, which was not practicable without purchasing and taking down a great number of houses and the aid of Parliament. This, tho' much wished for, he was not able to effect. The Commissioners for rebuilding the City had in the first place marked and staked out all the streets, and the Parliament confirmed their report, before anything had been fully determined about the design for the new Fabrick. The proprietors of the ground, with much eagerness and haste, had begun to build; accordingly an incredible progress had been made in a very short time; many fair and large houses erected, and every foot of ground in that trading and populous part of the town was highly estimated." It is here then stated, upon the authority of Sir Christopher Wren, that the axis of the new Cathedral was set more declining to the North-East than it was before. But how if the Cloister wall shows that the Nave declined to the South-East instead of the North-East? Sir Christopher Wren was not a man to be mistaken in a matter of East and West but he may have put down to irregularity, which he more than once mentions in connection with the Choir, the deflection of its axis, and with it the North-Easterly tendency of the whole Cathedral. These bearings are as follows:—

The New Cathedral to the North-East	6° . 28'
The Old Cloister wall and Chapter House to the South-East	0° . 53'
But the general axis of the Cathedral to the North-East	3° . 15'

That is on the assumption that the Oxford plan No. 1 correctly shows the correlation of the old and new fabric at the east end. That this was correctly marked on the plan, both at the east and west, I have scarcely any doubt; but as the whole of the foundations of the choir must have been removed, our only chance of proof from the spade will be in the possible discovery of the

foundations of St. Paul's cross, of which I by no means despair. But there is nothing unreasonable in the idea of a deflection of the axis. In the case we are contemplating, it must have been certainly large—not much less than 4°. There is, however, in a fine abbey church—Whitby—an instance very much more considerable.

To tabulate such cases as are known to me—	
Whitby	6° 20'
Old St. Paul's, hypothesis	3° 55'
Lichfield	1° 45'

St. Mary's, Oxford, has 3° 20' deflection. The above all incline to the north, which is the general direction; but there are instances of deflection to the south. Other cathedrals may be cited for a smaller amount from my own observation: I may name York, Norwich, Peterborough, and Lincoln, as designed by Bp. Remigius, but afterwards the axis was straightened by Grostete; also to a small but very perceptible extent St. Peter's Cathedral at Rome. If we assume the old nave to have been square with the west front, and that its central line was correctly shown on the plan, and then set it out on this hypothesis, not only do the cloister and chapter house agree very nearly indeed with their real places, but the south wall of St. Gregory's church falls centrally upon a piece of foundation, which was discovered in the alterations made six years ago at the west end. The strongest argument is to come. On the hypothesis that the position of the nave must be so, to be corrected, I a few days ago dug in the north churchyard for the traces of the north transept wall, and found them in the very first pit, within two

CLOISTERS AND CHAPTER HOUSE, OLD ST. PAUL'S.

feet of the centre of the hole. The whole of the work west of the tower is thus shown to be in accordance with the plan after correction in the manner above explained, and the axis of the transept agrees in direction with the plan, and all this comes by moving it on the western extremity of the axis as a pivot. We must conclude that the eastern extremity had the same relation to the present cathedral that the plan shows, and this implies the deflection of the axis of the choir. The deflection we are supposing could not have been continued without much inequality in some of the choir arches; some must have been spread out and others contracted. On this point we have Sir Christopher Wren's evidence, taken from the "Parentalia," p. 274, "Lastly the intercolumniations or spaces between the Pillars of the Quire next adjoining to the Tower are very unequal." This is exactly what must have occurred with a deflected axis. The Oxford plan, No. 1, shows the axial lines as coincident at the extremity of the old choir. This would seem a very probable arrangement. But in stating this we must not overlook the words of the Parentalia, quoted above, that Sir Christopher Wren took advantage of more room northward, &c. The Oxford plan, however, as it stands, shows a larger area of the new cathedral to the south of the old; whereas the amended plan gives the preponderance, although only a small one, to the north side. I claim, however, that the first purpose and end of that plan is that it was intended to show the axial deviations of the two cathedrals, and that it placed them at

the east and west extremities correctly, whatever it did elsewhere; and if so, there must have been the deflection of axis which I have spoken of. It is to be observed further that the plan as drawn shows the eastern wall very oblique to the axis of the cathedral, and the correction of the axis in the way proposed brings it very nearly square. Thus the only way to reconcile this plan with the new discoveries, if we retain the eastern points of coincidence, is by a deflection; and if there was no deflection, a plan which after a simple readjustment has proved itself accurate at the north transept must be entirely discredited as to its representation of the east end. The arguments against the deflection are the silence of Sir Christopher Wren on the point, and that straight axes are shown on this and in the other two plans, viz., Hollar's and Loggan's (for the Oxford plan, No. 2, lacks authenticity), and the words of the Parentalia that "The Surveyor took advantage of more room northward," may be quoted in this sense; but this last point is neutralised by the consideration that the same passage speaks of the axis of old St. Paul's as declining north of east, which would not have been true of an undeviated axis, for it has been demonstrated that the axis of the nave did not decline to the north-east at all. Besides the orientation would then have been so nearly true that he would scarcely have said it was not so without some qualification. The confirmation I hope for may perhaps come from the foundations of St. Paul's cross. This interesting structure is shown on the Oxford plan, No. 2, and the place is confirmed by several old perspective views. It is true that the plan we are now considering gives an impossible extension to the choir, but the compiler was probably influenced by Stow's figure of 690; but I think his place for St. Paul's cross about opposite the buttress dividing the second and third bay of the choir, and its distance from the cathedral itself may be allowed to have much weight, especially as he has rendered the due proportions of the chapter-house to the cloister, which neither Hollar's nor the Oxford plan, No. 1, have properly represented. The plan of the cloister (see opposite) shows the exact position of the foundations we have recently discovered, and their relation to the present cathedral. It will be seen they include the two southern of the eight great buttresses supporting the chapter-house, and of the internal cloister-wall, the four south bays of the east side, with the return angle, and also the south-western angle; besides these, traces were found of both S.E. and S.W. external angles of the cloister. I have a few remarks to make on the bells which have lately been added to the cathedral and hung in the north tower. This tower, although in the general view of the cathedral it does not seem a large object, now contains, all on one level, twelve bells, which Sir Edmund Beckett considers the heaviest peal that can be rung. The tenor is 62 cwt., and the total peal weighs about 272 cwt. The original floor, which seems to have been calculated for a much lighter peal, had in consequence to be strengthened. This has been done by powerful struts, two from each face of the tower, meeting in a quadrate collar arrangement, which strengthens the whole floor. The timbers are large, generally 18 inches deep, and some as much as 16 inches broad, either oak or of teak. The frame also is very solid. The effect produced by the swinging of the enormous mass of metal composing the peal is almost nil. I have, whilst the ringing was going on, placed my hand between the timbers of the frame and the stone work of the tower, and have felt nothing more than the slightest possible palpitating movement, very similar to that of my pulse and scarcely more perceptible. The bells were cast and hung by Messrs. Taylor, of Loughborough, and are the gift of the Corporation and some of the leading Companies of the City of London. The position of the scheme for the embellishment of St. Paul's is this: A sub-committee have recommended the adoption of a design left by Mr. Alfred Stevens for the pictorial treatment of the dome in mosaic. The President of the Royal Academy and Mr. Poynter have agreed to assist the Dean and Chapter and the committee in carrying out this design, with such modifications as the proper selection of the subject entails, and they are now considering the proper means of carrying out the proposal, which is to begin by a full-sized cartoon placed up in the dome itself, so that the scale of the work may be thoroughly settled and adjusted to its proper situation. This work, both preliminary and final, will neces-

* A Paper read by FRANCIS CHAMBER PENROSE, M.A., Past Vice-President, before the Royal Institute of British Architects, January 27th, 1879.

sarily take a considerable time. In connection with the embellishment of the Dome, it may interest the members to consider a very curious evidence of thought on the part of the skillful and scientific designer of the Cathedral, which I found when making the careful measurements of the configuration of the cupola which was requisite for this undertaking. These measurements for the section were taken with the help of the theodolite, and in several ways, so as to check, or I may rather say confirm, one another, so that I have no doubt of their accuracy within some fraction of an inch. Having got the measurements I was soon able to make out a system of three centres with radii about 67 feet, 46 feet, and 60½ feet, which afforded an exceedingly close approximation to the figure. But I spent a great deal of time in endeavouring to make out a law of design combining these centres and radii. At last it struck me that the arc of a parabola which should be a tangent to the sloping side of the drum at the springing, and of which the central line or axis of symmetry inclined to the horizon at an angle of $51^{\circ} 30'$, might afford a probable solution. These data, combined with the springing and culminating points of the Dome, enabled the elements, as they are called, of the curve to be calculated, and when done, although it differed a very little from the contour of the dome as executed, it explained the theory of the centres and radii which I had been seeking—absolutely. The correspondences are here exhibited:—

After adjusting the measured and the calculated dimensions at the bottom and top, that is at the springing point and the circular eye of the dome, we have for the equivalent heights	Feet.		Feet.
40-30,	$\left\{ \begin{array}{l} \text{a difference} \\ \text{in horizontal} \\ \text{measure of} \end{array} \right\}$.03	
" " " 13-40,		.00	
" " " 37-65,		.06	
And at the height of about 55-00 feet, where the horizontal measures have been equated, a difference in vertical measure of		.06	

The centres and radii are thus determined. If we first suppose the theoretical parabolic arc to be drawn and the angle formed between its inclined axis and the base of the cupola be bisected, namely by the angle of $25^{\circ} 45'$, the point where this line cuts the curve is taken as a given point in the section, and it is found that a radius of 66-60 feet with its centre on the springing line will join this point and the springing point of the cupola. Draw this arc and continue it upwards about half as far as below the point. If this centre be now joined to the point where the parabolic axis meets the vertical central axis of the dome, and the latter be taken for the centre of the second sweep, the junction of this with the first will be on this line produced. The radius will be 46-10 feet, and the sweep will extend 13° on each side of the parabolic axis, and then it will merge into a third sweep of which the centre is again on the springing line, and which will complete the section. The radius 66-60 feet is also the radius of curvature, as it is called, due to the parabola at the middle of the arc formed by its aid, and the last radius is also that due to the parabola at the termination of the whole section by the eye of the dome, and the central radius of 46-10 differs only a few inches from the radius of curvature at the apex of the parabola. The angle of inclination of the parabolic axis is the latitude of the place. The proof of the correctness of these views has been given by the practically perfect agreement between the calculations and the measurements given above, of which the discordances never exceed three-quarters of an inch, and I have compared many more points than are above tabulated, and have taken two complete sections of the dome with corresponding results.

The experiment at the Southampton docks has been lighted during the past week by the Wallace electric light. The shed is about 300ft. by 80ft., and is said to have been brilliantly lighted by three lamps, notwithstanding the absorbing effects of the black concrete floor and unwhitewashed roof. A single Farmer-Wallace light was also placed outside at the north-west angle of the open dock. No particulars have been made known as to the cost of the experiments.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At the meeting of the Institute held on Monday, the President, Mr. Charles Barry, in the chair, the following gentlemen were elected:—As Fellows: Alexander Peebles, Salter's Hall-court, Cannon-street, E.C.; Henry Dent Lomas, Norfolk-row, Sheffield; Thomas Archer, Buckingham-street, Strand, W.C.; Arthur Green, Buckingham-street, Strand, W.C.; Samuel Knight, Cornhill, E.C.; and William George Coldwell, Finsbury-place (South), E.C. As Associates: George William Webb, Castle-street Reading; Wallace Gill, Fountain-buildings, Bath; Henry Blackwell, Old Broad-street, E.C.; and Leonard Brisbane Brown, Aberdeen-place, N.W. The President read a communication from the Foreign Office stating that it has been decided by the King of Bavaria to hold quadrennial exhibitions of works of art at Munich; the first of these will open in July, 1879, and will close in October. The conditions would be placed in the hands of the secretary, who would afford all information to members, but he might add that first and second gold medals would be awarded to works selected by a jury of the artists of Munich; that all works must be delivered by the 31st May next; that the expenses of receiving and returning and insurance will be paid on all accepted works, but the expenses of those declined will fall on the owners.

ST. PAUL'S CATHEDRAL.

The President said Mr. Penrose's paper on St. Paul's Cathedral (see pp. 132, 133), was now open for discussion. The exact date of the mouldings of Old St. Paul's found, and how far they coincided in character with the received period of working, were questions which a few years ago would have excited the liveliest discussion in that room. As to the decoration of St. Paul's, all would be glad to know that the marble pavement had been commenced. The design exhibited was, he thought, an admirable one, and he could only hope that the whole work would be carried out as shown. It was a happy augury that two such masters of their art as Sir Frederick Leighton and Mr. E. J. Poynter had undertaken to prepare designs for the dome.

Mr. WHICHCORP inquired whether the tower was strong enough to bear the ringing of the peal of bells.

Mr. STATHAM wished to know what effect the proposed mosaics in the dome would have on the aerial perspective of the cathedral. One of the last things their late hon. secretary wrote upon was this point, for Mr. Cockerell thought the cartoons might reduce the apparent height of dome. He believed that the mosaic floors would partially neutralise this.

Mr. E. B. FERREY referred to the extraordinary variations in the contemporary views, plans, and descriptions of Old St. Paul's. The irregular intercolumniation which Wren condemned might have partially arisen from the practice of Gothic builders to set out the bays nearest a central tower to a narrower span than the others, so as to afford greater support to its mass. Again, there might have been a variation therein arising from different dates of building nave and choir. Mr. Penrose's theory of the deflections of the axes was very ingenious. The small size of the chapter house, only 33ft. diameter, was very remarkable in so large a cathedral, especially as compared with similar structures at York and Westminster.

Mr. DAWSON asked whether the cloisters were not truly square on plan. He also inquired whether Mr. Penrose had found any remains by which he could fix the coincidence of the east ends of the old and new cathedrals. If the plans were incorrect in this particular, there was no reason to assume that the axes of old nave and choir deviated.

Mr. ROBES suggested the question whether gilding and colour would not diminish the apparent size of the dome. Stevens's idea was to introduce into the dome groups of architectural ornaments from eight points, and to unite these by circles. The arrangement, size and colours of these rings would need the most careful consideration.

Mr. BOYES did not see from the plans and discoveries the necessity for Mr. Penrose's theory of deflections of axes in the nave and choir of old building.

The President, in closing the discussion, asked Mr. Penrose if, in his researches, he had found any similar cases in Classic or Gothic

work, where a dome was developed from three centres. It should be remembered that Wren always contemplated the introduction of colour into the dome, and that he probably made full allowance for it in designing. Mr. Penrose, in speaking of the deflection in Old St. Paul's, had referred to numerous other Gothic instances, all of which showed inclinations to the north. Now, the deep earnestness and feeling with which the Gothic architects worked, made it certain that there was a well-understood and common cause for the custom. A possible reason occurred to him, namely, that it might be a reproduction of the leaning of our Lord's head on the cross, shown in all representations as inclining to the right.

The Rev. BENJAMIN WEBB (hon. associate) said in his younger days he should have agreed with this hypothesis, but he believed any deflection was due to mistakes in setting out the foundations. If, however, this deflection was invariably to the north, the President's idea was probably right.

Mr. PENROSE said there were no grounds for alarm as to the effects of bell-ringing in so massively constructed a tower as that wherein the bells were hung. He believed the effect of filling the dome with mosaics would be to increase the apparent size. The two spandrels already treated seemed to him to look broader than the plain ones. The dome never looked so small as when there was a fog in it. The new pavement referred to in the paper was that of the crypt only, and not the nave, as several speakers seemed to assume. It had been prepared in the female prison at Woking from full-sized drawings which he had made; he thought the cost was about 4s. per foot, but this estimate was subject to correction. It was in contemplation to repave the cathedral floor proper as funds permitted. The old chapter house was a little larger than the drawings had led Mr. Ferrey to suppose; it was nearly 40ft. diameter. The old chapter house seemed to have been repaired and again used after the Fire, and Dr. Simpson, the cathedral librarian, had just found that in the reign of James II., meetings were held in the old room. The cloisters, as Mr. Dawson suggested, were not set out square; the bays of one side differed in size from those in the next, but corresponded with those opposite. He had fixed the relative position of the old and new east ends from the Oxford plan No. 1; he was now excavating to find the north wall. The peculiar curvatures of the dome appeared to have been determined upon by Wren, because a spherical vault appeared when viewed from beneath to hang down near the centre; the centres and radii he had shown were probably an after-calculation made for the guidance of the workmen in constructing the dome. The deflection of choir from nave was nearly always to the right (it was so at St. Mary's, Guildford, where it amounted to $3^{\circ} 30'$), but in a few instances, as at Wisbech, it inclined to the left. One reason for the deflection might have been a desire to improve the perspective by causing the distant lines of columniation to approach each other; the beauty resulting in this manner from the change of axis was very apparent in Lichfield Cathedral.

GREEK ART AND GREEK GEOMETRY.

A Paper by Mr. JOHN PENNETHORNE, entitled "The Connection between Ancient Art and the Ancient Geometry, as Illustrated by the Works of the Age of Pericles," was read for the author by Mr. Arthur Cates. The paper was written to show the connecting links between ancient art and the geometry of the Greeks, and to prove that complete harmony exists between the few passages in the writings of Plato, of Aristotle, of Vitruvius, of Philo, and of other authorities which refer to the theory of ancient art, and the facts deducible by measurement from the architectural remains in the Athenian Acropolis, which were calculated and executed by the architects of the age of Pericles. The works of the period were executed with such extreme precision that we are able from them inductively to recover the original canon of proportions of the Athenian porticoes by simply eliminating the small irrational quantities found to exist in the whole height of each temple and in the heights of steps, columns, and entablatures, when compared with the length of the upper step in any given portico, and by substituting instead the nearest commensurable magnitudes. When these small irrational quantities are effaced, all

the Greek porticoes harmonise, and can be calculated in what is really the given Athenian canon of proportions of porticoes. Thus: divide a line into 24 parts, and let the length of the upper step of the octastyle = 10 parts, of the hexastyle = 8 parts, and of the tetrastyle porticoes be = 6 parts. Let the whole height of the Doric porticoes = 5 parts. Let the whole height of the Ionic porticoes = 6 parts. In the Doric porticoes the whole height is found to divide into 9 aliquot parts: The height of the steps = 1, of column = 6, and of entablature = 2 parts. In the Ionic porticoes the whole height is found to divide into 12 aliquot parts: the height of the steps = 1, of column = 9, and of entablature = 2 parts. In the Doric and Ionic porticoes the total horizontal projection from the frieze to the lower step is made equal to 1-9th of the whole given height of the porticoes, then for the details of the steps, of the entablature, and of the inclination inwards of the first masses, the whole projection is divided into some given number of aliquot parts, and the details of the projections are regulated by these numbers. Great care was taken by the architects in the arrangement of the position of the propylæa, the roads of approach, and sculpture surrounding the principal designs, so as to suit certain points of view. The temples were generally surrounded by external colonnades supporting an enriched entablature, and the external appearance of the design was very carefully studied.

(To be Continued.)

THE LOGIC OF ARCHITECTURAL DESIGN.*

WITH ILLUSTRATIONS.

NOW, it is out of these three difficulties—that of getting the line of pressure within the flanking mass, of vaulting oblong spaces, and of maintaining bend near the keystone of the arch—that what is known as Gothic architecture grew. That pointed arches were first used for scientific, and not for aesthetic reasons, is clear from the fact that in the Transition or Romanesque churches all the large arches which carry weight are pointed, while the smaller ones introduced for ornament are round. Vaulting was now rendered a more easy matter, for the two arches could, if pointed, be struck from different heights, and yet form a good juncture, as in 13, 14. Upon this angle all the weight depends, so that it was presently noticed that this should be emphasised by a rib, and that the space between being of no structural importance, could be treated as the architect liked, by hollowing it out or setting the masonry askew. More and more ribs were added to the vaulting, as in Fig. 15, until the groining developed into the fan vault (Fig. 16), of which well-known examples exist in Henry VII.'s Chapel, Westminster, and at St. George's Chapel, Windsor. The last development marks a long and very important step, as will be seen from the plan of a fan vault. In this mode of groining all the ribs are of equal length, rise at equal distances, and diverge at equal angles. For the first time the vaulting is perfectly logical. The fan vault is such a pretty thing that it looks like mere play, and it has often been said to have been derived from an attempt to copy the interlaced branches of trees in a forest; nevertheless, it is the outcome of a couple of centuries' thought and experiment. In this last form of groining the fans themselves are mere ornament, disposed upon an inverted cone. What these would be like if unclothed with tracery may be seen in the roof of the approach at the High Level entrance to the Crystal Palace, which may be regarded as an engineer's conception of fan vaulting. In Figs. 18 and 19 we have made a comparison between the plans of Roman and Tudor vaulting. Another diagram shows a half section and half elevation of a Gothic building and a Roman building. In the latter building it will be seen that the walls run lengthwise, and the older Greek constructional forms are retained. In the Gothic building the walling is set edgewise, as buttresses, and arranged opposite the lines of stress. It would be quite possible to build a Gothic edifice as a simple series of buttresses supporting a groined vault, and, practically, many of the French cathedrals are

constructed in this manner, from a love of stained glass and a desire to obtain as much space as possible for its display. Owing to the thrust of vaulting it became necessary to bring more weight into buttresses, and this was the origin of pinnacles. From the elevation of a bay of a cathedral (Fig. 17) upon the wall you will see how strictly logical it is in arrangement and subordination of parts. But we must now pass on to consider the growth of the Gothic column and its capital. Fig. 20 shows the earliest form in which a circular column supports a square head and arcade, as at Waltham Abbey and a few other buildings. In Fig. 21 it will be seen that partly to get greater lightness in effect, and partly to allow of smaller stones being used, the upper arcade has been diminished at its base. The next change was to break the column up at Fig. 22 into smaller ones, so that the bulk is arranged just where the weight is required to be carried. In 23 the vaulting shaft is brought down at *b* to capital, and in 24 it is continued through to base of building, but bound in to the capital and column at *c*. In Fig. 25 you see a further and later example of grouped shafts upon a pier. It will be seen that it is perfectly easy to connect this last shaft with a Doric column by a series of gradations. The differences between the two are traceable to the relation between material and climate. The left-hand-side of plate VII. shows a Greek capital, built in a country where marble is abundant, where the climate was sunny and clear; hence the temple was fashioned with exact repetition in the two sides, and in the later Corinthian examples every detail was worked out with extreme delicacy. The Early English capital on the opposite side was executed under a thick climate, and in a coarse-grained stone; hence the several features were almost gashed out. That is the reason why the buildings in the Greek style, erected about 50 years ago, look so cold and uninteresting. Any attempt to reproduce that style in London would have this result, unless the Greek climate could also be introduced, and marble quarries opened, say at Redhill. But I must pass on to notice the logical influence of plan upon architecture. Upon the screen is a plan and perspective of the Houses of Parliament. This is a very fine plan in many respects. All the corridors converge in a central octagon, and this is architecturally expressed by the spire which rises in the middle of the building. The very large tower is placed at one of the angles to denote that this is the grand entrance. Now if Sir Charles Barry had been desirous of making his building in the first place symmetrical, and had put another Victoria tower at the other end (as I have heard some people say he ought to have done), he would in effect have said, "This is a building in which there are two grand entrances of equal importance." The clock tower is treated in a utilitarian manner as simply a means of raising a clock in the air. The lower part is therefore little more than a stalk, marked with emphatic vertical lines, and spread at the stage containing the clock. These towers are placed at the extreme ends of the building, so that it is possible to estimate its size from any standpoint. It would not be easy to find a better example of an illogical mode of construction than the building in which we are now assembled. As you know, on the front of the Institution next to Albemarle-street is a series of Corinthian columns. Internally it is, however, divided into a number of small rooms, and an entrance-hall and staircase leading to this theatre at the rear, and there is absolutely nothing to show that one portion of the building is of greater importance than another. The only logical building behind such a front would be one large square hall. Again, if you look at a section of St. Paul's Cathedral you will see that it is constructionally a Gothic building behind a Classic mask, with the masses disposed so as to rest upon a series of arched buttresses carefully tied in. But in the time of Sir Christopher Wren every building of importance must have the orders applied to it; it was then considered almost as unbecoming to erect a building without the orders as for a person to go without clothes. Upon the first a second order was erected at St. Paul's, and this is but a huge blank wall piled up to hide the flying buttresses supporting the central vault. On entering the cathedral you see this is the case, for there is a lofty middle vault and a low aisle on either side (in one of these you will recollect they have smothered the Wellington Monument). There is

another sketch on the screen; you will see that it is a part of a bridge, and that on a solid granite column set upon a buttress is a stone and timber house three or four stories high. The pier is substantial enough to carry a much greater weight, but now as I remove the upper sheet of the drawing you see that the granite shaft simply carries one of the recesses of Blackfriars Bridge! What a waste of architectural expression! Had the masonry been needed to increase the solidity of construction, it ought to have been disposed as a buttress in the line of the stream's flow, but as it is it simply carries an airy balcony. It is an instance of a mistake often made in engineering work. Our engineers will not learn anything about the principles of architectural design, and at the same time they will apply ornament to their works. If the materials were simply massed together in the lines and forms of greatest strength they would often look well, for they would approximate to the harmony of nature. Now I have spoken upon the true laws of architectural design, and have referred to some vulgarities of conception, and it may be asked what is the practical application to ourselves? During the past fifty or sixty years we have been taken up with the imitation of the various phases of past architecture. Roman, Greek, Gothic, in all their varieties—the last beginning, curiously enough, with Tudor, as that presumably most suited to modern requirements, and gradually worked backwards in the search for purity till something very like Norman was attempted—each has been tried, and the present fashion known by the name of that peculiarly æsthetic sovereign, Queen Anne, is just as illogical as any of the others. It is now correct to reproduce on your fireplace the façade of a Classic temple with the orders under an architrave, tympanum, and roof, all complete for the protection of the front from rain, and then you may scoop out the centre of the pediment to afford space for a bracket on which to set up a Japanese pot! And this is art in the house! The cause of these vagaries is that few people take the trouble to think what are the reasons for these things which they see every day, and consequently we are at the mercy of anyone who can get a new thing taken up by a few of the leaders of fashion. Architects are not entirely to blame for this; we can hardly hope for better architecture until there is a demand for it, and for this reason it is necessary that people of culture should be induced to think out the matter logically, to wish for what is right, and to say so. True, it is possible to live upright, moral lives, and even to be very happy while living in the midst of all that is unæsthetic. In the same manner a lady might be very charming, well-informed and possessed of natural attractions, but you would feel regret if she were to dress in so old-fashioned or unbecoming a manner as to make a "fright" of herself. The illustration applies to architecture at the present day. It is worth while to have our taste widened and cultured by examining into the reasons for details, and I shall consider I have done something for the advancement of architecture if I can induce such an audience as I have the honour of addressing to-night to give some attention to the architectural design.

At Stratford Police-court Mr. Martin, of Stratford-grove, was recently charged by the West Ham Local Board with erecting a building in Argyle-street, Plaistow, beyond the building line, and also with erecting the same without submitting the plans for the approval of the Board department, was fined £5, and a continuing penalty of £1 per day was imposed until plans should be supplied which could be approved of.

The council-chamber in the Guildhall, Derby, has been rearranged and rendered more commodious. The woodwork and fittings were executed by Mr. Morley, of Forester-street, and the upholstery by Messrs. Cochrane and Dean, also of Derby.

Mr. G. C. Ashlin, architect, of Dublin, has been elected an Associate of the Royal Hibernian Academy of Arts.

A new workhouse chapel was recently opened at Orsett Union-house, South Essex. It has been erected by Mr. Wilder, contractor, of Gravesend, from the designs of Mr. Charles Pertwee, of Chelmsford. It seats 120 people. The altar, desks, seats, and roofing are varnished pine. Above the altar is a reredos of three panels of slate, the centre one gilded with a cross on a ground of French grey, and the other two with sacred monograms. It is heated by hot water.

* A lecture delivered by HENRY HEATHCOTE STATHAM, F.R.I.B.A., at the Royal Institution, January 31st, 1879. [Concluded from p. 160.]

COMPETITIONS.

MATLOCK CHAPEL COMPETITION.—There were 183 applications for instructions in the above competition, and 85 sets of designs submitted. The plans were to be sent in on or before Feb. 1st to Mr. J. S. Holkinson, Secretary. At a meeting of the committee held on the 5th inst., it was decided to award the first prize (£20) to the design bearing the motto, "Thorough," and the second (£20) to "Liverpool, January, 1879." The authors of the first prize design are Messrs. Dixon and Moxon, of Barnsley. The proposed outlay is £2,500, and the chapel is to accommodate 400 persons. From a letter in another column it will be perceived the competition appears to have been decided in a very unsatisfactory manner.

ILKESTON BOARD SCHOOLS.—The Ilkeston School Board have provisionally selected the following architects as competitors for the proposed Granby schools to accommodate 300 boys and 300 girls in separate departments, together with teachers' residence:—Mr. A. S. Potter, Mansfield; Mr. Knight, Nottingham; Mr. Keeling, Nottingham; Messrs. Trueman and Pratt, Nottingham; and Messrs. Tait and Langham, Leicester.

THE METROPOLITAN FREE HOSPITAL COMPETITION.—Little has transpired since our last notice of this competition. The Committee have had under consideration, the claim made by Mr. Owens, referred to by us, and having consulted their assessor, Mr. P'Anson, have determined to adhere to their first decision. Mr. Owen's plan possesses merit, though not of a kind to justify a redistribution of the awards. The design "Civis" (Mr. Charles Barry's) has been supplemented since our last notice, by a coloured perspective of the Bishopsgate-street Elevation, showing the alternative design for this front. It is certainly less faulty than the first; red brick and stone are used, and a slight balcony projection obtained up to the top of second floor. The elevation is crowned by a broken ornamental gable, in which the angle quoins are pronounced features. We may notice *en passant* that the Jews' convalescent room, kitchen, and nurses' room are a long way from the wards, and on the third floor the middle ward is made a passage room, to the extreme transverse wards at either end. These are objectionable points. We may add to our comments as regards "Experientia," that though the wards are only lighted on the Half Moon-street side, the author has provided ventilating spaces above the rooms on the inner side, by keeping the ceilings low. In justice to the author we point this out. We understand the committee have been very anxious to acquire the property at the corner, Sir Paul Pindar's house, which breaks into the site, and has considerably curtailed the possibilities of the plan.

LEGAL INTELLIGENCE.

ALLEGED NEGLIGENCE AND BREACH OF CONTRACT.—The Metley School Board v. Gough and Pattinson.—This was an action for negligence and breach of contract, tried at the Leeds Assizes on Saturday and Monday week. Messrs. Pattinson contracted with the plaintiffs to erect two schools, the cost of which was about £5,000. Mr. Gough was the architect. The schools were ready for opening in 1877, and it was then discovered that the contract had not been carried out. The material was of an inferior quality, and the work was an entire departure from the character of the specifications. Mr. C. L. Dresser, C.E., Mr. Geo. Cowson, Ald. Croft, and another witness were called on the part of the plaintiffs to prove that the work was inferior, and not according to the specifications. On behalf of the Messrs. Pattinson, the builders, it was contended that the final certificate of the architect was conclusive. The contract provided that a certificate of the architect showing the final balance due should be conclusive evidence of the works having been duly completed. It was admitted by the plaintiffs that such certificate had been given, and the learned Judge thereupon intimated that he considered that there was no case against the defendants Pattinson, and he directed a verdict to be entered for them. As to the defendant Gough, the architect, the Judge (Lord Justice Brett) said the question was whether he had exercised reasonable care in superintending the builders. Mr. J. P. Seddon said he had carefully examined the schools, and he considered, with the previous witnesses, that they were substantially and satisfactorily erected. He had in a letter to the *Times* recom-

mended the use of slates similar in colour to those used in these schools in the restoration of St. Alban's Cathedral. Mr. Crawford Eyre, who was clerk of the works in the erection of the schools, gave corroborative evidence. Mr. Pattinson, the builder, and Ald. Croft were also called. His Lordship asked the jury to decide whether Mr. Gough had exercised reasonable care and skill in superintending the execution of the contract and in giving the final certificate. The plaintiffs had not impugned the honesty of Mr. Gough's intentions, therefore that consideration would not be necessary, and so far the defendant was entitled to a verdict. The jury returned a verdict for the defendant. His Lordship gave judgment accordingly.

Building Intelligence.

BRIGHTLINGSEA.—The parish church of Brightlingsea, near Colechester, was reopened on Wednesday week after undergoing repairs and restoration. It is a noble Perpendicular edifice, with a lofty tower which serves as a landmark. The roof of the nave and chancel, together with the clerestory, having fallen in about the year 1814, the present roof was then constructed, and at the same time the chancel and chancel aisle arches were rudely rebuilt. Recently the church had fallen into a grievous state of dilapidation. From the designs and under the superintendence of Mr. Charles Pertwee, of Chelmsford, the tower arch has been opened into the nave, the west window and ancient ringers' gallery have been restored, the nave rebeneched and paved, gutters renewed, and roofs of aisles repaired, piers and arches scraped, and walls repaired and coloured, chancel arch rebuilt, and window-glazing renewed. The chancel has also been furnished with choir seats and other appointments, and has been decorated in stencel. An organ has been erected by Messrs. Bryant and Ellis, of London, and the church is now heated by Portway's slow combustion stoves. The works have been carried out by Messrs. R. J. and W. Aldous, of Brightlingsea, at a cost of about £900.

LONDON.—New show-rooms at No. 13, King William-street, Charing Cross, for Messrs. John Hardman and Co., have recently been completed by Messrs. Lott and Son, builders, under Messrs. John and S. Flint Clarksons; the principal show-room, which is 48ft. long and 24ft. high, being on the street level. All the walls, ceilings, and floors are lined with pitch pine in narrow widths; recesses are left, which Messrs. Hardman will fill with typical decoration. The cases throughout, which are dustproof, are of polished wainscot, some of them being iron-plated and guarded by electric alarm-bells. The packing-rooms, &c., are paved with thick Claridge's asphalt. The tubes and the brass, and wrought-iron cages for them, and other work in the gas fittings are from special designs, and have been made by Messrs. Hardman themselves; as also the door furniture and other metal finishings. They have also executed the stained glass exhibited in the lantern lights.

FOLKESTONE.—A new church at Foord, an outstanding district of the parish of Christ Church, Folkestone, was consecrated on Feb. 3rd by the Bishop of Dover. The church, which, when complete, will consist of nave, aisles, chancel, organ chamber and vestries, tower and spire, is built in the Early Decorated style of Architecture, with the local ragstone laid in random courses, with Box-ground Bath stone dressings, the internal walls being lined with rich, coloured, red brickwork, coursed with grey. The roofs are of fir, left clear, without stain or varnish. The windows are glazed with varied tinted cathedral glass. The seating is of red deal, varnished only. The heating with hot air has been most successfully carried out by Mr. John Grundy, of Tyldesley, near Manchester, and has borne the test of the recent severe weather with very satisfactory results. The whole of the works have been carried out from the designs and under the superintendence of Mr. A. Rowland Barker, architect, 11, Buckingham-street, Strand, London. Mr. Burgess Reeves, architect, Folkestone, acting as clerk of works. The building works have been carried out by Messrs. R. and D. Baker, of Tontine and Harbour-streets, Folkestone, at a cost of about £3,500.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

F. Bros.—S. and S.—L. and N. W. R. Co.—B. Bros.—E. T. H.—T. W. C.—M. and Co.—J. and J. B.—M. R. Co.—B. W. M.—W. P.—H. S. B. Co.—W. W.—B. and B.—R. E. C.—T. and H.

BUILDER. (Yes, of the Secretary of the R.I.B.A., 9, Conduit-street, W.)—JINK. (See ndvt. pages.)

H. R. (Indiarubber can be dissolved in mineral naphtha or in bisulphide of carbon. Take the light-coloured parts from the bottle-rubber and cut into fine shreds. Keep the mixture in a warm place, and the rubber will soon dissolve.)

TYRO. (Your comrade is right. It is quite true there are 144 square inches in a superficial foot, but in duodecimal or cross multiplication the inch is taken as the 12th part of a foot, for it really means 12 square inches. The sum of the superficiais given is 175ft. 6in.)—**FAIRBANKS.** (We can recommend a little book entitled "Practical Architecture," by W. Scott Burn, published at office of the *Country*.)—**A "YOUNG ARCHITECT"** (It is best to mount the print on linen stretched to a frame, and to keep the surface of engraving a little away from glass by a gold fillet.)

"BUILDING NEWS" DESIGNING CLUB.

LIST OF SUBJECTS.

A. A cottage hospital for five of each sex, containing convalescent wards, administrative offices, rooms for matron, surgery, and operating-room. Plans and elevations to an eighth-inch scale. A view may be substituted for one elevation.

B. A mantel-piece with pier glass over, which may be combined with shelves for china. Material painted wood. The fire place to have an open grate. Height of room 9ft. 6in., and width of chimney-breast 5ft. 10in. scale.

DRAWINGS RECEIVED.—G. Jacz Bach (we shall be glad to receive your designs, and we hope you will profit by our criticism.) "J. C." in circle, H. Ray, L. in G. Fleur-de-lis, W. J. M., East Anglian, Omnia Vincit Labor, Signum, "Motto J," "G" on shield, "Nemo" in shield, J. Crowquill, T. W. P. (you, like many more, violate the rules in not keeping all your drawings of one subject on one sheet; members are requested to be more particular in this respect), Rebus, Yes or No, Burswell, Try, Demwich, Leo, Rusticus, Thor (your sheet is not of specified size), "M" with leaves, "Be to its faults a little kind," &c., J. S., Spero Meliora, J. Lennox Canning.

Correspondence.

A VERY LIMITED COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—The enclosed is very amusing; you will observe the covert flattery conveyed in the remark, "Your name was one of those mentioned," &c., suggesting the idea that only a select few are to be allowed to compete; but notwithstanding the selectness of the affair, architects must satisfy Mr. Fairbairn by referring to churches already erected by them, and at the same time that gentleman will be glad to get a "note of their terms." I would advise the successful architect to get paid early in the day, as after erecting a church (with tower and spire) to hold 700 people, and hall, boundary walls, &c., very little will remain for that unfortunate man out of the magnificent sum of £3,500. I presume you will agree with me that the architect who engages in this competition has lost all idea of personal and professional dignity.—I am, &c.

Edinburgh, Feb. 6, 1879.

SOUTH U.P. CONGREGATION, GALASHIELS.

It having been resolved to proceed with the erection of a New Church for this congregation, I have been requested by the Managers to procure and submit to them plans by a number of architects for approval. Your name was one of those mentioned to the Managers, and I was instructed to ask you to provide Plans, and to inform you that they had resolved as follows, viz.:—(1), That accommodation should be provided for 700 sitters; (2), That the Church should be after the Gothic style, with spire and bell; (3), That there should be a hall and all modern conveniences in keeping with the Church; (4), That heating should be by water; (5), That sittings (gallery on three sides) should be in circular or horse-shoe form; (6), That platform-pulpit, and accommodation for choir and organ or harmonium behind same, should be provided; (7), That interior should be of yellow pine; (8), That when estimates come to be taken they must be by way of specification, not by schedule; and (9), That the total cost, including boundary walls, &c., and also Architect's fees, must not exceed £3,500. The site secured for the Church is a prominent one, and consists of 80ft. of frontage and about 115ft.

in depth. As it is expected, however, that there will be houses built on both sides, the sufficient lighting of the Church must be kept in view. If you agree to furnish Plans, you will probably be good enough to refer me to any churches of similar construction erected by you or to your plans, in order that their acoustic properties may be tested. As time is of importance, all Plans must be lodged on or before the 15th instant, and it will of course be understood that no charge is to be made for any Plans, except for the Plans which may be adopted, and I shall be glad to receive at same time with the Plans a note of your terms. Should you wish to see the site of the proposed Church, either Mr. Munro, the chairman of the Managers, or I, shall be glad to point it out to you, and to give you any further information you may desire.—I am, Sir, your obedient servant,
F. C. FAIRBAIRN, Clerk to the Managers.
Galashiels, Feb. 4, 1879.

GLOUCESTERSHIRE LUNATIC ASYLUM COMPETITION.

SIR,—I inclose you copy of correspondence relating to the above competition, and will feel obliged if you can find space for insertion in your next issue.

I am at a loss to understand the Building Committee's reasons for refusing to furnish necessary information to competitors. One would reasonably expect them to correct any errors in their "Suggestions to Architects," to which their attention has been drawn (see "Queries 8, 9, 10").

It is very unfortunate that the Committee should shirk their duty, and thus leave competitors in the dark as to their requirements, especially as the "conditions of competition" appear to be fair and reasonable.—I am, &c.,
Durham, Feb. 11, 1879. WILLIAM FOX.

[COPY.]

GLOUCESTERSHIRE COUNTY LUNATIC ASYLUM COMPETITION.

Durham, January 23rd, 1879.

Dear Sir,—I enclose a Schedule of Queries in connection with the above, and will feel obliged if you will kindly fill in answers and return to me at your earliest convenience.—Yours truly,
The Clerk of the Peace. WILLIAM FOX.

Shire Hall, Gloucester,

7th February, 1879.

SIR,—The Building Committee of the proposed Gloucestershire Lunatic Asylum have decided not to furnish any further suggestions or replies to queries to architects.—Yours truly,
FRANCIS EDW. GUISE,
Clerk of the Peace.

W. Fox, Esq., C.E.

(per G. M.)

[We cannot spare space for the list of queries sent, but they are all such as ought to have been answered, and without the information asked for in many, competing would be working at random.—ED.]

WESLEYAN CHAPEL COMPETITION AT MATLOCK BRIDGE.

SIR,—Plans for the above having been asked for in competition, it appears that eighty-five architects responded, the plans being sent in on Saturday, Feb. 1.

On the Monday or Tuesday following the committee were enabled, by their very superior judgment, to decide which of the eighty-five sets were the best, and also which was the second best!

In my simplicity I should have thought that it would have taken some time to arrive at a fair and reasonable selection out of so many designs, but perhaps the solution of the matter may be rendered more easy (as it seems the selection was) by taking into consideration that one set (the first premium) was furnished by the near relation of one of the Building Committee, who is also a large contributor to the funds.

Putting these facts together (the short time taken for the selection, and the relationship of the successful competitor), and considering that there were twenty or thirty superior designs received, can there be any reasonable doubt but that the whole thing has been a prearranged affair? I confess I looked for better things from a set of people who profess to be guided by righteousness and truth in all their dealings.

Further, the instructions were minutely particular on the subject of cost, absolutely stating that they would utterly discard any plan that exceeded the amount named, whereas it is the opinion of competent local and other authorities that the selected design would cost about double that amount, while many excellent designs submitted could undoubtedly done for the money.—I am, &c.,

ONE OF THE UNSUCCESSFUL 83.

METROPOLITAN FREE HOSPITAL COMPETITION.

SIR,—May I ask the insertion of a few words of explanation with regard to your criticism on the design "Experientia"?

Not wishing to dissent from its general tone, the writer will find he is in error about the question of cross ventilation to the wards, as it is provided throughout by the means of light directly accessible to the outer air, obtained in the difference of height between the wards and corridors, a plan I believe novel in its application.

I enclose you a small section making it fully clear.

As to the mode in which some of the competitors have acted, that is to unite their forces and thereby obtain a large selection from alternative designs, I will say nothing except that it is novel, but I have my very grave doubts whether the pavilion design of "Ad Rem" comes within the conditions of the competition, and in any event a building of such excessive height can hardly fail to be in its practical working unsatisfactory.—I am, &c.,
"EXPERIENTIA."

PENMAENMAWR, OR BLUE WELSH STONE.

SIR,—Since your issue of Jan. 31, Mr. Allison has kindly forwarded me a copy of the report on Granite Paving referred to in his *exposé* of the Neven Granite Company's Circular in yours of the 17th ult.

He has also favoured me with an explanation, and this, with his complete report dealing more fully with the whole question, convinces me that it was never intended to condemn the particular Penmaenmawr stone which comes under the denomination of "Grey Welsh."

I shall feel obliged, Sir, if you will insert this in justice to Mr. Allison, who I think you will allow is entitled to praise for the public spirit displayed in preventing (with your assistance) corporate bodies and others, who have not the opportunity of obtaining authentic information on this particular subject, from being misled.

I venture to express an opinion also, that his report, if published, would be of interest to those studying the question of the best material for carriage-way paving.—I am, &c.,
MATTHEW JONES, City Surveyor.

Chester, Feb. 5, 1879.

HOTELS AND RESTAURANTS.

SIR,—Through the medium of your journal may I be allowed to supplement by a few remarks, Mr. Frederick Francis' able paper on the above subject, read before the Architectural Association? Referring to the art tiles employed as decorations at the King's Head, may I, as one of the two actual painters of this work, be allowed to state, that I have just designed and painted those additional portions rendered necessary by the enlargement of the premises in Mark-lane.

I must here acknowledge the name of the other painter, M. Alexandre Gravin, who in the original and largest portion of the work designed and painted those tiles constituting architectural arrangements, flowers, birds, fruits, &c., the sole painter and part draughtsman of the entire historical Shakespearian, and other subject work being your obedient servant,
ISAAC A. GIBBS.

I. A. Gibbs & Howard, 64, Charlotte-street,
Fitzroy-square, Feb. 10, 1879.

ENGLISH v. AMERICAN LOCKS.

SIR,—In your paper of last week you insert a letter from Mr. Hill respecting American machine-made locks. Without venturing to say a word against those of Messrs Chubb's manufacture, we may yet, with perfect confidence, recommend those supplied by Mr. Hill, for cubicles and school buildings, for which they are particularly applicable.

The locks are certainly superior to the ordinary cast-iron rim locks. Each lock is numbered, and two keys are supplied with the lock, and in case these are lost or mislaid fresh keys may be obtained by sending the number to Mr. Hill. Besides this, the shank of the key is flat, and not round, as is usually the case with English locks. The consequence is that they are much lighter and easy to carry. At all events, we find both locks and keys have given much satisfaction to our client for whom the school boarding-house at Tonbridge has been erected.—We are, &c.,
WADMORE AND BAKER.
35, Great St. Helens, E.C., Feb. 10, 1879.

Intercommunication.

QUESTIONS.

[5676].—**Orders of Architecture.**—In setting out the orders for workmen, it is considerable labour to go into the very particular parts of modules and minutes as generally given in books. I have in my possession, "Nicholson's Carpentry," published at the beginning of last century, containing a treatise on "The Orders." The plates are very practical, as each of the parts shows at a glance the relation it bears to the others by a series of divisional lines by the side of elevation. Thus, take the Corinthian: the first line would be divided into 94 parts representing diameters; in the second, 11-6 parts would be marked for the capital, and a part for base and plinth, and so on with the smaller members. These plates are rather rough, and I am anxious to obtain a modern work of a similar nature. Will any reader kindly refer me to one?—C. B. C.

[5677].—**Body Colour.**—I have been colouring some large surfaces with body colour; and although whilst wet the tint appears perfectly flat, I find it dries very unevenly, leaving unsightly patches here and there. Will some one kindly give me a hint or two, and greatly oblige?—ONE IN THE DARK.

[5678].—**Painting Cement.**—Having to repainting some cement plinth and cornice, we should be glad if and one would inform us of some material that would stand the weather, and prevent the damp from coming through. What has been done before has, in a short time, peeled off in patches.—W. J. A. E.

[5679].—**Gilding Plaster Casts.**—I have a plaster copy of the celebrated "Milton Shield," same size as the original, and think of having it gilded and framed. Can any of your readers inform me: 1. Is it a proper treatment to gild it? 2. Will the gilding stand, or is it likely to get discoloured or fade? 3. Who had I better get to do it, a picture-frame gilder, or is there a special treatment for plaster casts? 4. Would silvering it be best, to make it more like the original, and would the silvering stand as well, or better, than the gilding?—TYRO.

[5680].—**Clerk of Works' Salary.**—If an architect employ and pay the salary of a clerk of works by request of his client, is the architect entitled to a profit on the outlay?—A. R. I. B. A.

[5681].—**Voluntary Architectural Examinations.**—I am thinking of going in for examination next year, but feel doubtful about the meaning of some of the points mentioned in the instructions to candidates, and should feel very much obliged if any passed candidate would be kind enough to enlighten me. In the first place, with regard to history and literature, "An outline of certain characteristics of the principal historical styles of architecture." How many styles is this to include? Would Greek, Roman, Gothic, and Renaissance be taken to represent a sufficient number, or are more or less required? Next, "The particular characteristics and history of any one style named by the candidate." Should one say Classic, or Gothic, as the case may be, or be more definite and say Greek, or English Gothic, or Thirteenth Century English Gothic (say) or what? There is not sufficient time allowed to admit of any very comprehensive history. Further, in the work to be done at home, "A specimen detail drawing to an inch scale of the work in each trade, and an equal number of full-size drawings to correspond." Now how many trades are to be represented? How is "each" to be interpreted? Would mason, carpenter, and joiner be sufficient? If not, how many trades must be exemplified in this manner?—TYRO.

[5682].—**Cubic Space.**—What is the minimum cubic space allowed to each person in the following buildings, viz., model dwellings in flats (exclusive of staircase), public places of worship, and hospital wards?—HEXAGON.

[5683].—**Cymagraph.**—I wish to have a cymagraph made. It was described by Mr. M. B. Adams and Mr. Sharp in the BUILDING NEWS for 1873. Will some of your readers oblige me with full particulars? What size should parallelograms be from rivet to rivet, and is it indispensable that they are both the same length, width, and thickness of brass bars, diameter of hook, size of board and box?—R. S. T.

[5684].—**Fixing Tiles.**—Can any kind reader inform me how I may fix tiles of 4in. thick at the back and sides of a dog-grate? I have, on several occasions, fixed them where described in various cements, &c., suggested; but at the longest, they remain in position only for about 12 months, being affected, no doubt, by the heat. As the tiles are valuable, I am desirous of fixing them, and any suggestions to aid me in so doing will much oblige.—CALOA.

REPLIES.

[5682].—**Casts of Carving.**—Mr. Harry Hems' statement that pipe-clay is obtained principally near Chudleigh, is calculated to mislead. It is found in the neighbourhood of Newton Abbot, in which town and the neighbouring village of Kingsteignton the clay merchants have their places of business. The trade is entirely in the hands of five or six firms.—J. B.

[5000.]—**Sea-Washed Road.**—The method I should pursue would be to form groynes so as to assist the accumulative power of the tide. These may be formed of the most available material and placed at tolerably close intervals. As deposit takes place the spaces between can be gradually filled up. An embankment of brushwood at the outer side of roadway would be, perhaps, more expeditious, a bank being gradually raised as the materials are to be found. But if no other materials are at hand, the road will necessarily take a certain time to form.—G. H.

[5001.]—**Builders' Charges.**—If there were no plans nor specification, the builder asked to tender has unquestionably a claim, unless there was an understanding that he was to submit a tender at his own risk. It is a question, however, whether a charge for quantities made for the tenderer's own convenience can be made. I think not.—G. H. G.

[5002.]—**Carrying Weights of Bridges.**—To find the carrying weight, it is necessary to obtain roughly the weight of structure itself, adding to this the moving load. If the brick or stone is of good quality, and the arches sound, one eighth of the above load may be safely placed upon it. Much depends on foundations, centre of arch, abutments, besides the crushing resistance of the arch stones, and no rule could be applied without a knowledge of these.—G. H. G.

Our Office Table.

SOME curious particulars transpired last week in the Exchequer as to the manufacture of picture groups of noted people or gatherings. A Mr. Ridley, who called himself an artist, had painted a number of bodies of various sizes and in different attitudes for a photographer named Tuck, who was subsequently to fit heads to them. A dispute arose about an unfinished painting of bodies, which, when supplied with heads, was to represent the Pan-Anglican Synod. The photographer said he was to see a sketch before the picture was proceeded with, but the jury thought the contract was completed, and gave Mr. Ridley the verdict.

A meeting of the Edinburgh and Leith Engineers' Society, held last week, a paper was read by Mr. John Romilly Allen on the "Stability of Dock Walls," in which he described the methods by which failure in dock-walls might be avoided, instancing specially the necessity for the geological formation of the site being studied by means of borings taken during the progress of the work. He stated that by means of careful backing a great economy in masonry might be effected, and that the stability of the wall was greatly secured by having increased batter at the foot, so as to spread the pressure over a larger area at the front of the foundation, where the stress is greatest. The paper concluded by a new method of calculating the stress on a dock-wall, which was simple and practical.

At the fortnightly meeting of the Liverpool Engineering Society, held on Wednesday, Jan. 29th, Mr. M. E. Yeatman, president, in the chair, a paper was read by the Hon. Sec., Mr. W. W. Squire on "The Construction of Timber Dams." The paper dealt with two forms of coffer dam, viz.: Double sheet piling with clay puddle between the rows of piling; and single sheet piling caulked and shored up on the inside. The details of each were described and illustrated by diagrams based upon the most recent practice. Pile driving was fully entered into, together with the preparation of the timber for piling. Various shoes suitable for this particular work were described, and their comparative cost given. Some particulars of the lengths of timber that can be obtained were given, and the wearing of piling was discussed. Caulking was next considered, and the paper concluded with some remarks upon drawing piles and the removal of the clay by dredging.

THE freedom of the Turners' Company was presented on Monday to Sir F. Leighton, the President of the Royal Academy, and Mr. Charles Manby, the Secretary of the Institution of Civil Engineers. Sir F. Leighton, in his reply, reminded his hearers that it was to the earliest application of the principle of the lathe—the potter's wheel—that the world owed the greatest sum of delight and instruction in varied, expressive, and decorative forms. What a fund of loveliness was in the pottery of the most gifted artistic races, and what a mine of character in all. What an instructive contrast there was, for instance, between the bulbous homeliness of British earthen vessels, and the tapered elegance of the produce of Japan and Persia, or the more balanced perfection of the pottery of Greece. It seemed to him as far as artistic temperament is concerned, one might read the character of a people in its pots and pans. But if we further

considered what we owed indirectly to the potter in the artistic adornments of which his art has been the vehicle—when we remembered that the vase-painting of Greece had brought us into more immediate contact with the genius and intimate life of the supreme artistic race than the greatest achievement of its sculptors—we should more fully feel our debt to that humble potter's wheel which, with a past sense of its importance, the turners had so prominently painted on the blazon of their company.

THE forthcoming part of the *Transactions* of the Royal Irish Academy for their department of Polite Literature and Antiquities is devoted to a memoir, by Dr. Graves, Bishop of Limerick, on a remarkable Ogham inscription, found on a stone monument from the Kilteen of Aghlish, a disused burial ground, in the parish of Minard, in the county of Kerry. The monument, in addition to the Ogham inscription, has also inscribed upon it an Irish cross. The outline of this cross is formed not by straight lines, but by arcs of circles, and the cross itself is surrounded by a circle. Examples of it occur on fifth or sixth century Christian monuments in Ireland, and it may be seen worn on the breasts of Irish children on every anniversary of St. Patrick's Day, whence it is often called Patrick's Cross. The question of the probable origin from an Eastern source of this form of cross is discussed in the memoir. There is also to be found on this monument a remarkably disguised form of a cross, known to antiquaries as a *swastika*. The Ogham characters are distinct, and the Bishop has little doubt as to reading them as follows—"MAQ MAQA—APLOGOD," the first two words being on the right, the third being on the left hand side of the stone. A great deal of interest attaches to the determination, after very careful consideration, that the third word is the Ogham equivalent of Aedhlogodh, which is the genitive case of a well-known proper name belonging to a chieftain living in the sixth century, and in the neighbourhood of the place where the monument was found.

MR. WILLIAM HAYWOOD, Engineer and Surveyor to the Commissioners of Sewers for the City of London, has reported to a committee of that body on those parliamentary projects of the present session which affect the City. These are but six in number. The Metropolitan and Metropolitan District Railway Companies introduce a fresh Bill for the completion of the Inner Circle *viâ* Cannon-street, Great Tower-street, and the Minorities, with a spur line to White-chapel High-street. The scheme provides for the widening of the eastern end of King William-street and Eastcheap, and Great and Little Tower-streets in case the Corporation, Commissioners, or Metropolitan Board of Works contribute towards the cost. The London, Chatham, and Dover seek to extend their Holborn Viaduct station nearer to Old Bailey by acquiring some 16 perches of land. The City Union Railways (Outer and Inner Circles Completion) Bill, which proposed to construct an above-ground line from Cannon-street to Fenchurch-street stations, and an underground line from Mansion House to Aldgate has been abandoned. The City Corporation are promoting two Bills, one for the abolition of Leadenhall Market, and the establishment of a new market in lieu thereof, the improvement of the site and neighbourhood and the formation of a new street from Leadenhall-street to the junction of Lime and Fenchurch-streets; and the other for widening London Bridge about 11ft. on each side and improving the approaches. The last Bill is that for the Tower High Level Bridge, promoted by the Metropolitan Board of Works. The Commissioners are recommended to dissent from the whole of the projects in order to obtain a *locus standi* before Parliament.

WE have seen a new blind roller, patented by Mr. W. Luce Hosking, of Ventnor, which is simple, and yet an improvement in many respects on any other we have seen. It is a wooden roller, which can be made in any length, of two halves, semicircular in section. When the two halves are brought together the rib fits into the groove, and between these parts, and over four or more pin points in the bottom half of the roller, the top edge of the window blind is gripped, and the whole secured by a sliding latch, the roller being then round, and in appearance solid, with the blind hanging from one point of its diameter. The cord-holder is a small

circular box, about the size of a halfpenny, for screwing to the window frame; the cord passing down perpendicularly from the roller is threaded through the holder, and when the blind is required to be raised, is pulled down freely, or when lowered is allowed to run up through it. When, however, the blind is wanted to remain to any height up the window, the cord is pulled a little to the right by the thumb and finger, and catching against a loose jaw or cam inside the holder, the cam rises and grips the cord between it and a raised surface inside the cord-holder, till it is again relieved by the thumb and forefinger. The cord can never slip (till required), or the blind run down by its own weight, as with the double cords and rack, as the tighter the pull is on the blind the firmer will be the hold on the cord, which, working between smooth surfaces when in motion, cannot fray or wear. The blind-roller and cord-holder when used in conjunction allow of the blind being raised almost as easily as with a spring roller, without the evils attendant upon the latter. The brackets which support the axles of the roller are similar to the ordinary kind, but one is fitted with an adjusting screw and lock-nut, so that if, through the sinking of foundations a window-frame falls at either corner, the roller can be adjusted in its bearings in a few seconds to remedy this, and allow the blind to properly cover the window.

WE have seen the clay model, executed by Mr. Belt, the sculptor, for the proposed statue to Lord Byron, at the artist's studio, 21, Wilton-plaee, Belgrave-square. The poet is shown seated on a rock, in an attitude of contemplation, his right arm resting upon his knee, supporting his head. A manuscript lies open on his left knee, while in his hand is a pencil. Lying by the side of the rock is the poet's favourite dog, "Boatswain," looking up devotedly into his master's face. We think the sculptor has been successful in the treatment of the dress. There is a careless grace and ease in the lines of the figure and adjuncts. The poet is clad in the customary loose shirt, the expression of the face is thoughtful, and the model is at least broadly treated, dignified, and thoroughly English in conception. Mr. Belt's work has been suggested by the well-known lines from "Childe Harold":

'To sit on rocks, to muse o'er flood and fell,
To slowly trace the forest's shady scene
..... This is not solitude.'

The sculptor has consulted the best authorities for the likeness, and the model is colossal, on the scale of a 9-feet figure. It is intended to place the bronze easting on a marble pedestal 10 feet high, and this is to be given by the Greek Government. As regards the site, we understand nothing has yet been finally settled. The top of St. James's-street, the Green Park, and other localities, have been suggested. Mr. Belt is also engaged on a bust of the late Hon. Eliot C. Yorke and Mr. G. H. Whalley.

THE subject of the work prepared for distribution to the subscribers to the Art Union of London of the present year, is a series of twenty illustrations, by Mr. C. B. Birch, of Lord Byron's poem "Lara," with the text. This poem was chosen for illustration on account of its presenting a large amount of dramatic incident within the limits best suited for a work of this character, thus facilitating the aim of making a series of designs which should, as far as possible, tell their own tale. In addition to this, great advantages are offered by the costume and architecture of the probable period suggested. Mr. Birch is already well known to the subscribers by his statuettes, "A Wood Nymph" and "Whittington." The original marble of the former, life-size, given in 1872 as a prize by the Art Union, was selected as one of the works to represent British sculpture at the Paris Exhibition.

CHUBB'S

WROUGHT IRON DOORS,

Fire and Thief-Resisting Strong Rooms, Safes, and Iron Linings.
CHUBB'S PATENT LOCKS.

THREE PRIZE MEDALS

And Honourable Mention at PARIS EXHIBITION, 1878.

Lamplough's Pyretic Saline is refreshing,
most efficacious, and the preventive of FEVERS, RHEUMATISM,
SMALL-POX, SKIN DISEASES, and many other spring and summer
ailments. Sold by chemists throughout the world, and the
Maker, 113, Holborn Hill. Use no substitute.—[ADVT.]

CHIPS.

The restoration of some church paintings at Ecouché (Orne) has brought to light a masterpiece by Mignard, nearly 9ft. in length, which had been missing since the Revolution. Some house-painter apparently had daubed a picture over it.

The ceiling of the nave of St. Katherine Cree church, Leadenhall-street, now undergoing repairs, is decorated with the arms of the senior sixteen livery companies in proper heraldic colours. It is proposed to renovate this exemplification of the companies' arms in connection with the reparations now in progress. The church was built from the plans of Inigo Jones, "citizen and clothworker," in 1628.

New Roman Catholic schools have been commenced at Crewe. Eventually it is proposed to build a church adjoining the schools. The architect is Mr. James O'Byrne, of Liverpool, and the contract, which is of the value of £3,117, has been given to Messrs. Roberts and Robinson, also of Liverpool.

It is rumoured that Mr. Cross contemplates the extension of the Artisans' Dwellings Act to the smaller towns. We doubt if much good is likely to come of the change unless action on the part of the local authorities is made compulsory, and that is not likely to be done by the present Government.

The foundation-stone of a new Presbyterian church at York was laid on Friday last. The cost is estimated at £5,000. The architect is Mr. T. B. Thompson, of Hull, and the contractors are Messrs. Keswick, York.

By special permission of Her Majesty, Mrs. Thornycroft is making, for the Art Union of London, a reduced copy of her fine portrait-bust of H. R. H. the late Princess Alice. A number of copies, in porcelain, will form a part of the prizes in the coming distribution.

The west window of the parish church of High Wycombe has lately been filled with stained glass representing three subjects in the life of our Lord—viz., the "Nativity," the "Adoration of the Magi," and the "Presentation in the Temple." The window is the work of Messrs. John Hardman and Co.

The town council of Derby have increased the salary of Mr. Clement Dunscombe, the borough surveyor, to £350 per annum, as surveyor to sanitary authority, in addition to £150 paid from the corporation.

The Wrexham rural sanitary authority have approved plans prepared by Messrs. Shone and Baugh, civil engineers, for the sewerage of the districts of Stansty and Acton. The outfall is to be on land at Erlas, belonging to Lord Kenyon, and the estimated cost is £4,500. The same authority has obtained the sanction of the Local Government Board to a loan of £5,600 for sewerage works at Brymbo.

Winsham parish church, near Chard, has been reopened after a restoration carried out under the superintendence of Mr. W. Hodder, architect to Viscount Bridport, by the workmen on the estate.

The Aldershot School Board have approved plans of alterations and additions to the West schools, to be carried out at an estimated cost of £1,000.

The death is announced of Mr. William Turner, architect, of Wrexham, at the early age of 42 years. Amongst his works are several churches, chapels, and a number of board schools, and the cemetery chapels at Wrexham.

A cathedral is about to be built by national Russian subscription at Andijan, in memory of Prince Sergius Maximilianovitch, nephew of the Emperor of Russia, who was killed in the late war.

It is stated that Lambeth, Vauxhall, Chelsea, Albert, and Battersea bridges will be opened toll free on March 1st.

An adjourned quarter sessions of the Bedfordshire magistrates was held on Tuesday week to consider tenders for the re-construction and improvement of the Shire hall. Sixteen tenders were received, ranging from £13,030 to £17,699, and the lowest but one, that of Messrs. Wood and Son, of Leeds, was accepted on the recommendation of the architect, Mr. Alfred Waterhouse, A.R.A. The amount of the contract—£13,485—includes fittings for the court-room. The work is to be commenced at once, and to be completed in fifteen months' time.

The floor of the chancel of St. Michael's church, Nottingham, is being laid with encaustic-tile pavement. The work is being executed by Mr. Crossley, of Newark. A stained window is about to be placed in the west end of the same church.

An infectious diseases hospital and disinfecting chamber have been erected for the Taunton Town Council, and are now ready for occupation. The work has been carried out by Mr. Westcombe, contractor, under the supervision of Mr. J. H. Smith, borough surveyor.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Institution of Surveyors. Paper by H. J. Castle, sen., on "Contributive Value," 8 p.m.

Society of Arts. Cantor Lecture No. 1, Dr. Cortfield on "Household Sanitary Arrangements," 8 p.m.

WEDNESDAY.—British Archaeological Association. Papers by Rev. C. Collier, on "The Recently Discovered Roman Villa at Iken Abbas," and by George Patrick, on "Burleigh House," 8 p.m.

Society of Arts. Paper by J. L. Haddon, ex-Chief Engineer in the Ottoman Service, on "Turkish Resources and their Ready Development," 8 p.m.

THURSDAY.—Society for the Fine Arts. Conversazione.

FRIDAY.—Institution of Civil Engineers. Paper by Percy W. Britton, Esq., on "The Design and Construction of Wrought Iron Tied Arches," 7 p.m.

HELLIWELL'S Patented NEW SYSTEM OF AIR&WATER-TIGHT IMPERISHABLE GLAZING. All Woodwork is covered, and no outside Painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

"It is suitable for Railway Stations, Mills, Weaving Sheds, &c., but is specially applicable to Conservatories, Plant Houses, and Orchard Houses, and we should be very much inclined to try the system. It is certainly worth looking to."—*Builder*.

"And will, in our opinion, supersede any other similar system before the public."—*Building News*.

"It seems to meet the end in view more nearly than anything we have seen yet."—*The Field*.

"The patent has given high satisfaction to every one using it."—*The Christian Union*.

"Convincingly prove the new Glazing System to be worthy the attention of readers of the 'Keystone.'"—*The Keystone*.

For Estimates, Drawings, or Particulars, apply to the Patentee, T. W. HELLIWELL, Brighouse, Yorkshire; or, 19, Parliament-street, London.

WHITLAND ABBEY GREEN SLATES

These SLATES are of a grey green tint, are stout, and made in all sizes. A large stock available for immediate delivery. For further particulars (with a list of important buildings covered) apply to the MANAGER, Clynderwen, R.S.O., Carmarthenshire.—[Advrt.]

Holloway's Ointment and Pills.—All ulcerations, sores, abscesses, bad legs, and skin diseases are best treated by these medicaments. The ointment eradicates all noxious taints and makes every symptom assume a milder form, and this desirable result is made doubly certain by the purifying, regulating power of the pills.

HIGH-CLASS VARNISHES.

READE BROTHERS, Tower Varnish Works, Wolverhampton, respectfully invite attention to their Varnishes for House Painters, Decorators, and Builders, which will be found of uniform excellence, and for elasticity, lustre, and durability all that can be desired. They would direct special attention to their Extra Hard-Drying Varnishes for church seats, and seats of schools and public buildings, which for hard-drying, brilliancy, and wear are unsurpassed.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.
Agent: Mr. E. CRICKMAY, 4, Agar-street, London, W.C.

Trade News.**WAGES MOVEMENT.**

BANGOR.—The bricklayers and masons employed at Bangor struck on Monday, owing to the masters' demand for an extension of working hours until four o'clock on Saturday afternoon.

BOLTON.—The Master Builders' Association of Bolton have given notice of the following great reductions in the building trade:—Bricklayers, plasterers, plumbers, and painters with labourers, will be reduced, bricklayers, 3d. per hour; labourers, 2s. per week; plasterers, 3s. 8d. per week; labourers, 3s. 9d. Plumbers who worked 48½ hours all the year round at 35s. weekly will be required to work 52 hours in summer and 47 in winter, at wages of 34s. 8d. summer and 31s. 4d. winter; and painters will be reduced from 8d. to 7d. per hour. The joiners submitted to a reduction some months ago.

BLACKBURN.—The master painters of this town have issued notices for the further reduction of the wages of operative painters at the rate of 3d. per hour, equivalent to 2s. 3d. per week, to take effect on Monday next. The hands have proposed arbitration, but this has been declined by the employers. It is not expected that the dispute will end in a strike.

DURHAM.—On Saturday week the Durham joiners struck work against a reduction in their wages of 3d. per hour. The men were receiving 73d. per hour, but the building trade is so depressed that the masters allege they cannot compete with contractors at the existing rate of wages. A compromise was offered by the deputation of workmen to continue work at a reduction of 3d. per hour. This the masters refused, and after a long and animated meeting of the men, it was unanimously resolved to stand out against the full reduction.

GLASGOW.—About 250 plumbers in Glasgow, who have been on strike for six weeks, agreed on Monday to accept a reduction of 1d. per hour on the present rate, 83d. per hour.

PRESTON.—The Preston stonemasons resumed work on Monday morning on the masters' terms, a reduction of 4s. per week within a fraction.

SOUTHPORT.—On Monday week the Southport painters came out on strike to resist a reduction in their wages of 12½ per cent. The men had offered to refer the dispute to arbitration, but the masters declined. At present painting is just beginning to be brisk, and the strike will interfere with contract work.

TODMORDEN.—Wages have been generally reduced in the building trades of this town by 3d. per hour. A strike has occurred at Mr. Mallison's, builder, of Vale Mill, who put up a notice of a reduction of 1d. per hour.

CHAPPUIS' PATENTS

FOR

REFLECTING LIGHT.—DAYLIGHT REFLECTORS

OF EVERY DESCRIPTION, ALSO

ARTIFICIAL LIGHT REFLECTORS.

P. E. CHAPPUIS, Patentee. Factory, 69, Fleet-street, London, E.C.

N.B.—DIAGRAMS AND PROSPECTUSES ON APPLICATION.

TENDERS.

BRECKENRIDGE.—Stabling at Wild's Rents, Bernondsey, for Mr. C. Morgan. Mr. J. Leaning, architect:—
 Ryder £3,423
 Patrick 3,023
 Tongue 2,884
 Tarrant and Sons (accepted) 2,653
 Greenwood and Sons 2,646
 Sheppard 2,625

BRIDGEMOUTH.—For repairs to the grammar school for the Bridgmouth Town Council:—
 Bates and Head (accepted) £48 7 -
BRIGHTON.—For the construction of the Hornington sewer for the Town Council:—
 Jotter (accepted) £1,253
 [Six tenders received.]

BLACKBURN.—For the sewerage of the districts of Wotton and Livesey for the Blackburn Town Council:—
 Read, G. and J. E. (accepted).

BEDFORD.—For the reconstruction of the Shire Hall, in Bedford, for the Bedfordshire county magistrates. Mr. Alfred Waterhouse, A.R.A., architect:—
 Wood and Son, of Leeds (accepted) £13,485
 [Sixteen tenders received, of which the highest was £17,690, and the lowest £13,030.]

CAMBERWELL, S.E.—For the enlargement of the boys' and girls' departments of the Camberwell-road school, by 300 places, for the London School Board. Mr. E. R. Robson, architect to the board:—
 W. Brass £3,769
 J. Tyerman 3,600
 B. E. Nightingale 3,580
 W. Tongue 3,580
 S. J. Jerrard 3,383
 J. Thompson 3,380
 Wall, Bros. 3,375
 W. Downs 3,333
 Higgs & Hill (accepted) 3,290

[Cost per head of enlargement only, £92s. 9d. Cost per head of entire school (as far as ascertained), £11 11s. 2d.]

CLIFTONVILLE.—Tenders for an additional story to the Sussex Hotel, Cliftonville, Brighton. Mr. Fred W. Hyde, architect; quantities supplied:—
 Cheesman £1,489
 Lockyer 1,447
 Garrett 1,380
 Botting 1,300
 Parsons and Son 1,275
 Hatching and Son 1,185

CROYDON.—For repairs and decorations at Haling Park, Croydon, for Mr. James Watney. Mr. H. J. Newton, architect:—
 Grimwood and Sons £845
 Godden 813
 Lambie (accepted) 793

DERBY.—For founding and erecting a water wheel at Souter's corn mill, for the Derby Corporation:—
 Lampitt and Co. (accepted) £900

FARNHAM, SURREY.—For paving crossings at the foot of Castle-street, Ashley-terrace, and at the railway station:—
 Diamond £105
 Mosher, G. 103
 Duke & Fowler (accepted) 101 10s.

HOLBOAN.—For dusting and watering during the current year for the Holborn District Board of Works:—
 Jackson and Son, Hornsey £3,500
 Hobbs, T., Paddington 3,200
 Dodd, H. 2,650
 Williamson, W. T., King's-cross Wharf 2,774
 Irons, W., Dulston (accepted) 2,490

LOOE.—For the erection of a schoolmaster's house, for the School Board for Looe, Cornwall:—
 Honey, J. (accepted) £322
 Lowest of seven tenders received, of which the highest was £450.]

LLANDDOGET.—For the erection of a schoolmaster's house at Llanddodget, for the Rev. Thomas Jones. Mr. W. E. Jones, architect, Bryn Llanwrst:—
 Jones, Jeremiah £320
 Jones, John 250
 Jones, John Berth (accepted) 270
 Williams, Evan 270
 Griffith, Wm. 260
 Hughes, Wm. 268

LLANWRST.—For the erection of two cottages in Watling-street, Llanwrst, for Mr. William Owen. Bodunig Cottage, Llanwrst. Mr. W. E. Jones, architect, Bryn Llanwrst:—
 Jones, Jeremiah £218
 Jones, David 190
 Griffiths and Edwards (accepted) 200
 Williams, Evan 205
 Williams, Robert 203 10 0

LEA.—Tenders for restoration of north aisle, St. Giles's Church, Lea, Malmesbury. Mr. C. J. Phipps F.S.A., of London, architect:—
 Light and Smith, Chippenham £1,830
 Wall and Hook, Brinscombe 1,726
 Restall, Bisley 1,702
 Stratton and Knapp Garsdon (accepted) 1,500
 F. Brown, Tethury 1,375

MAIDEN HEAD, BERKS.—Residence for P. S. Langton Esq., Norfolk-park. Messrs. Brown and Albury, architects, Reading:—
 Kempell £2,625
 Flewood 2,525
 Simmonds 2,494
 Silver and Son 2,464
 Woodbridge Bros. 2,280
 Kingerlee (accepted) 2,150

MARYBOROUGH.—For repairs and decorations to the Town Hall, for the Town Commissioners:—
 Haynes (accepted) £275 10s.
 [Three tenders received.]

NEW CROSS.—For new kitchen, &c., at the Amersham Arms, New Cross-road, for Mr. W. Agate. Mr. W. T. Hunt, jun., surveyor:—
 D. Thomas £270
 M. Redman 248
 H. L. Holloway 230
 R. Smith (accepted) 198

PENOE, S.E.—For gas fittings in the new parochial offices, for the Penze vestry. Mr. Elkington, architect:—
 Stude & Co. (accepted) £91 12s. 6d

RED HILL.—For the erection of shop and dwelling-house and two cottages in Commercial-road, Red Hill:—
 Apter Bros. £865 0 0
 Worsford 823 16 0
 Stoneman and Son 720 0 0
 Seougal, T. (accepted) 665 16 0

ROTHERMERE.—For paving Laxford-street, for the Rotherhithe vestry:—
 Rutty £220
 Turner, T. 188 10s.
 Etheridge, W. 184
 Kent, C. (accepted) 178
 Wells & Barnes 155 10s.

SOUTHEAST-ON-SEA, ESSEX.—For constructing sewers in Porter's town for the Southeast-on-Sea Local Board. Mr. Harrington, surveyor:—
 Maxwell, W. £1,200
 Day, C. R. 1,198
 Storey & Co. 1,136
 Bell, J. 962
 Bulford, G. 879
 Whurr, T. 705
 Strachan, J. 610
 Steward, W. 598 10 8
 Spenderlow, W. (accepted) 540

TOOTING.—Tenders for the erection of the Defoe Memorial Manse, at Tooting. Messrs. Tarring and Wilkinson, architects, 69, Basinghall-street, London, E.C.
 Gough, London £905
 Atkinson, Wandsworth 795
 Manley, M., London 787
 Langridge and Sons, London 750
 Lovell, E., London 750
 Castle, W. and H., London 721
 Lawrence, T., Mitcham 715
 Morris, D., Tooting 700
 Behington, Uxbridge 690

TOTTENHAM.—For constructing a new sewer in West-green-road, for the Tottenham Local Board of Health:—
 Bell, Wood-green £458
 Bloomfield, Tottenham 450
 King, Herne-hill, and Humphreys, Tottenham 385
 Rowley, West-green 355
 Pizze, Crouch-end 345 10 10
 Ford and Norris, Wood-green (accepted) 340

WOOD GREEN.—For the construction of roads, sewers, and surface-water drains, on the British Land Company's Estate, at Wood Green. Mr. Henry B. Mitchell, Surveyor:—
 Koehle £2,756
 Jackson 2,696
 Acock 2,657
 Harris 2,655
 Crockett 2,625
 Killingback 2,580
 Pizzezy 2,550
 Dunmore (accepted) 2,491
 Richardson (withdrawn) 2,200

WALSALL.—For new receiving wards and alterations to the union workhouse for the Walsall Poor Law Guardians:—
 Taylor, Thomas (accepted) £720

[Lowest of thirteen tenders received, of which the highest was £932; architect's estimate, £790.]

BATH STONE OF BEST QUALITY.
WESTWOOD GROUND, BOX GROUND, CORSHAM DOWN, and COMBE DOWN.

RANDELL, SAUNDERS, & CO., LIMITED.
Quarymen and Stone Merchants.
 Prices, delivered at any part of the United Kingdom, furnished on application to
 Bath Stone Office, CORSHAM, WILTS.—[ADVT.]

Epps's Cocoa.—GRATEFUL AND COMFORTING.—“By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected cocoa, Mr. Epps has provided our breakfast tables with a delicately-flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly-nourished frame.”—*Chief Service Gazette*.—Sold only in packets, labelled—“JAMES EPPS & CO., Homoeopathic Chemists, London.”—[ADVT.]

THE BIRKBECK BUILDING SOCIETY'S ANNUAL RECEIPTS EXCEED FOUR MILLIONS.

HOW TO PURCHASE A HOUSE FOR TWO GUINEAS PER MONTH
 With Immediate Possession and no Rent to pay.—Apply at the Office of the BIRKBECK BUILDING SOCIETY, 29 & 30, Southampton-buildings, Chancery-lane.

LONDON, FRIDAY, FEBRUARY 21, 1879.

NEW RENAISSANCE BUILDINGS.

THE inclination of the last new fashion in building is by no means exclusively towards the Stuart or Jacobean style, if we may judge by recent works in the metropolis. If we walk down the Embankment, up Northumberland-avenue, to Charing-cross, we meet with three buildings, all executed in some version of the Renaissance, though illustrating very different schools. Taking Mr. J. P. St. Aubyn's and Professor E. M. Barry's new block of chambers in the Temple, we are struck by the fact that two gentlemen of totally opposite schools are engaged jointly in the work. The design by the first-named gentleman was Gothic, a view of which we gave some time ago; but the erected façade towards the Embankment is French Renaissance, and is the work, we believe, chiefly of Professor E. M. Barry. The connection of the two gentlemen is not difficult of explanation. The new block is an extension of the Harcourt and Plowden buildings, and Mr. J. P. St. Aubyn has acted for the Middle Temple, and Mr. E. M. Barry for the Inner Temple, or Harcourt structure. It being necessary to make one elevation, it was determined to adopt the design of Professor Barry, and the result is a structure of Renaissance character, in which the Gothic element of variety has been mainly kept in view. Indeed, there is much in the outline and massing of the present building which reminds us of Mr. J. P. St. Aubyn's first sketch. The broken frontage and the agreeable contour and skyline are essentially Gothic. The angle turrets are not capricious features, but intended to give a certain æsthetic result, arising out of an accidental circumstance of plan, and those who are still fond of asserting that Classic design cannot be made picturesque in its masses, need only to look at this building to see what is possible, even in London, when there is plenty of room, and when the restrictions of the Metropolitan Board do not unnecessarily interfere. We may mention that a necessity became, perhaps, a virtue in this respect. The Board refused to allow the frontage to go beyond the old river wall, and to save a wasteful setting-back of the line of front, the façade forms an acute angle with the return on the eastern side, and a slightly obtuse one on the west. To conceal the effect of the perspective lines, angle turrets were introduced, and the result must be pronounced satisfactory. One great advantage certainly the architects here have had, and that is the building can be seen in the front and at both ends—an opportunity seldom to be met with in London. The end façades have also bay windows, and that towards the gardens facing Blackfriars is flanked by a circular turret in the line of the older buildings which serves to mark the limit of the façade on this front. The main façade is symmetrical; it has a slight projection in the centre crowned by an ornamental gable in the style of the French châteaux of the time of Francis I., on either side is a spacious bay window, each of these being marked by lofty gables which break the steep mansard roof. The only fear we have is that the smoky atmosphere of London will not take kindly to the fine carved panelling and detail, which in parts begin to look smothered in black. The corner turrets, with their ogee roofs and crocketed angles, are made useful features in the plan, and they finish above the cornice as open peristyles. Examining the building, we

find it comprises two distinct wings or extensions parallel to each other and separated by a court. The wings are united in front, and make one façade. This is done by a centre archway in the façade leading into the court, above which are large rooms alternately approached from the Harcourt and Plowden wings. Each wing contains several sets of chambers to be exclusively used for the members; and each set consists of four or more rooms, a laundress closet, water-closet, and safe. On the Middle Temple side there are two sets of chambers on each floor, making on all the floors fourteen sets. The Inner Temple wing consists of three sets on a floor, in all twenty-one sets. We notice a little ingenuity has been exercised in the planning of the rooms near the front on account of the unsquareness of the site. A few of the larger rooms with bay windows are turned into octagons in plan, and the passages are rather crooked. On the Harcourt side two open wells give light to some of the inner rooms, and in one or two instances the lighting is indirect and insufficient, though the staircases are all lined with glazed bricks. The stairs are of stone, and are lighted from the centre court. The floors are constructed on the Dennett arch system, and the principal sanitary arrangements have been carried out by Mr. Jennings. In the Middle Temple chambers Mr. Jennings' plan of ventilation has been adopted, we are told, successfully. It consists of air-chambered flues opening into the rooms. Dust shafts are also provided to the floors, and every convenience seems to have been consulted. The façade and its profusion of carved work are the chief attraction, as internally the chambers are plainly finished with plaster for painting. Passing under the centre archway we notice symbolic carved keystone and spandrels, and the piers and window friezes are enriched with carved medallions. Over gateway forming the central line of mullion of façade are figures representing Valour, Truth, and Clemency, and at the sides are symbolic carvings of Moses as the Moral Law-giver, the Queen as Modern Law, and Minerva at the top. Panels of the Virtues, the Sciences, Commerce, and Navigation are also introduced. On each side of the entrance arch niches are left for figures of "Justice" and "Learning," which are being executed, we hear, by Mr. Calder Marshall, R.A. The other carving is very spirited. We may add that the clerk of works is Mr. Geo. Goodchild, to whom we are indebted for some particulars, and that the contract was taken by Mr. G. W. Booth. By adopting the Renaissance of the early period, the architects have overcome the rigid forms and inelastic features of a purer Classical style, and have made their building harmonise with the Temple Gardens and picturesque masses of brick houses. The formality of the Roman or Palladian would have been out of place, the Gothic would have blended incoherently with the library of Mr. Hardwick, and the "Queen Anne," though akin to the old hall and a few of the houses, would have appeared somewhat incongruous with a spacious thoroughfare so thoroughly modern in its conception as the Embankment. The type of Renaissance chosen is eminently Gothic in its spirit and outline, and the architects appear to have taken as their model the Chateau de Chambord, in which we trace many of the details employed. The horizontal lines are emphasised, but the vertical lines are not lost. The carved and panelled pilasters which flank the windows are made to play a subordinate part, being purely decorative, while the balcony of the first floor is made a prominent line and is deeply and massively corbelled. The basement is rusticated and has a batter at the angles. One of the best features is the cornice and the dormers, the profuse carving and members of which produce a very rich, though not redundant effect.

In Mr. Gibson's offices for the Society for the Promotion of Christian Knowledge a more Classical mode of treating the façade is adopted, and it is only fair to observe that here the limitations of site imposed a rigid line of frontage. But the author, notwithstanding, has been fortunate in giving variety to the fenestration and ordinances by adopting a single order for the two principal stories, and in otherwise diversifying the windows. Instead of superposing four or five orders with their entablatures answering to the number of stories, a very common mode of applying the Classical style, the elevation is divided into three—a basement of one order comprising the chief offices, a predominant order, and an attic. This is by no means new; the principle was largely employed by the architects of the time of the earlier Georges—cleverly in Somerset House; but it became rather hackneyed, as we find it in some of Nash's buildings in Regent-street, Eaton-square, and many of the neighbouring squares. The monotony of the practice arose from masking a common brick front with commonplace windows, behind a screen of three-quarter columns or pilasters, above which the front, in all its naked baldness, peered as an attic story. Mr. Gibson has avoided this appearance by recessing some of the planes of his walls, and in producing a play of light and shadow. There is certainly a freedom in the detail; the usual cornice members to the basement story, which is rusticated, are dispensed with, and bands of guilloché run round the broad faces. The treatment of the attic in the main façades is satisfactory, giving variety in a part of the building that is generally spiritless and lacks interest, and the architect introduces in the cornice a peculiar though somewhat favourite means of relief by a diaper in the cove. On the whole, the corner frontage has been dealt with in a masterly manner, though some exception may be taken to the enrichments.

We have already noticed the architectural treatment of the Grand Hotel, in which a very different working out of the Classic régime is observed.

REMBRANDT'S ETCHINGS.*

COLLECTORS of Rembrandt's etchings, especially in England, have much cause for thankfulness to Mr. C. H. Middleton for his excellent and comprehensive catalogue of the works of the greatest master of the Dutch school. The life of Rembrandt Van Rhyen has been much obscured by the many misstatements of those who have written about him: most of the stories told to his discredit have been proved to be fictitious. He was born of respectable parents in easy circumstances, in the year 1607, as is proved by the register of his marriage, which took place upon the 22nd of June, 1634, when he calls himself twenty-six years of age, as his birthday was on the 15th of July. Having no turn for classical studies, he was taken from school at an early age, and placed with a painter to learn the principles of the art. Having been instructed further by Jacob I. van Swanenburgh and Lastman, he studied at last, according to Houbraken, under Jacob Pinas, but this fact requires corroboration. Having already achieved considerable success, in 1630 he settled at Amsterdam. Here he married his first wife, Saskia, the daughter of Rombertus Van Ulenburg. In or about 1640—possibly in expectation of a sum of money upon the death of his mother—he purchased a house situated in the Sint Antonie Breedstraat, and in it executed most of his finest works.

Mr. Middleton thinks it not unlikely that the purchase of this house was the first cause of the ruin that overtook the artist in

* A Descriptive Catalogue of the Etched Work of Rembrandt Van Rhyen. By CHARLES H. MIDDLETON. London: John Murray, 1878.

1637. It is of great importance that we do not confound this house with a smaller one which he occupied previously. It was of this larger one that the story is told of his having so large a number of pupils constantly paying him 100 florins a year, the upper rooms of it being divided into small chambers by screens so that the pupils might be kept separate. In 1642, his charming wife, of whom he made so many portraits, died, and from this date a perceptible change takes place in all his work; but notwithstanding the graver tone which is apparent, he still worked on as hard as ever, or harder still. In 1653 he married again, and, becoming deeper and deeper in debt, in 1658 he was made a bankrupt, and all his splendid collection of prints, pictures, and drawings, of armour, of dresses, and rare china was dispersed. The house was stripped of everything, mention having been made of even the half-dozen linen articles at the washerwoman's. From this time the history of the artist becomes obscure. We find that about 1665 he was again a widower and again married. Whether he, as report says, ever went to Sweden or England is uncertain. Evidence goes far to prove that he never left the town in which so much of his life had been spent. He died at Amsterdam in October, 1669, and was buried at the Westerkerk. The arrangement of his etchings is new, and should commend itself to all students. The fact of the great variety of the quality of work exhibited in different examples of the master's etchings suggested to the author that it would be best to rearrange the whole of the etchings according to the dates of execution, so that the student might understand easily that works of apparently different hands were really by the same hand at different periods. In these days of reckless scepticism, when it has become the fashion for so-called connoisseurs to show their acuteness, by their supposed discoveries of alien work in so many of the earlier and larger etchings, this arrangement will prove very instructive. To prevent confusion and difficulty of reference, a full table of all the etching-work of Rembrandt, in the order of date of execution is prefixed to the volume, the numbers of the five principal catalogues being placed in columns opposite.

The descriptive catalogue is arranged in three parts: (1) Studies and Portraits; (2) Scriptural and Religious; (3) Fancy Compositions; each preceded by a list of the works included in the section. After the description of each print we have accurate measurements in inches and millimeters; the various states (not always allowing trifling alterations to determine a different state); and the principal old copies that could by any means mislead the unwary. Reference is made in each example to the public collections in which it may be found, and, in cases where it has been thought advantageous, critical notes upon technical, controversial, or other matters of interest are added.

Mr. Middleton goes very fully into the question of Rembrandt's making money out of etchings, done by pupils, and inscribed by himself, and as to how far he was legitimately assisted. He proves conclusively that the early etchings, when he was probably almost without pupils, and before he had great reputation, could have brought him little profit. "It has been constantly and confidently asserted," says Mr. Middleton, "that Rembrandt continually altered his plates, working up and producing new states, the charge being usually combined with an accusation of avarice and dishonesty. . . . But the conclusion at which I have arrived is in entire contradiction to this usually-received opinion. Rembrandt very rarely altered his plates; when he did so it was solely for an artistic or other such intent—he corrected an obvious error, supplied an unintentional omission, or added that which

he knew was an almost necessary improvement. Alteration for the mere sake of alteration; still more alteration through greed of profit, was entirely foreign to his habit, and wherever a change is effected which does not recommend itself to us, and is unworthy of his genius, I do not hesitate to affirm that an inferior hand has wrought upon his plate."

Without always agreeing with Mr. Middleton in the instances he brings, there is no doubt that he is usually a safe guide. The variations which disfigure Rembrandt's later prints were doubtless made by others into whose hands the plates fell after his misfortunes. There is little chance that he was allowed to retain his valuable copper-plates when they took from him the linen which was at the wash. The book concludes with a list of the works consulted and an ample index. There are twelve plates, of great value, of tests by which to discover the various states and copies. No collector will be without a copy of this valuable book, which is alike creditable to the writer and the publisher. Nothing has been spared to do justice to the importance of the subject.

ARCHITECTURAL GEOLOGY.—IV.

POIKILITIC series. This name has been given to the strata which come between the Oolites and Lias and the Carboniferous rocks, on account of the *variegated* colours, which are their distinctive feature; they consist chiefly of red clays, shale, and sandstone in the upper part, with beds of limestone and dolomite, or magnesian limestone, below them, the upper beds being called "Trias" or "New Red Sandstone and Marl," and the lower beds the "Permian," or more commonly the "Dolomitic," after the French geologist, Dolomieu. The Poikilitic series may, therefore, be considered as forming the boundary between the Secondary and Primary rocks, since the Trias belongs to the former and the Permian to the latter division.

Triassic rocks present a remarkable contrast to those of the Lias, both in the red colour which prevails in most of the beds and the small amount of organic remains and carbonate of lime found in them; consequently it is hardly correct to apply to any of them the term "marl," which signifies a calcareous clay; but as the name of "Red Marl" has been commonly given to the upper beds of the Trias, it will be necessary to retain that designation in distinguishing them from the lower beds, which have received the name of "New Red Sandstone." The Trias beds come prominently to the surface in the counties of Cumberland and Northumberland, West Lancashire, and Cheshire, the north-eastern parts of Yorkshire, and over a large portion of Nottingham, Warwick and Worcester; also in the counties of Stafford, Leicester, Derby, Gloucester, Salop, Glamorgan, with small portions of Somerset and Devon.

New Red Marl consists chiefly of red clay with beds of alabaster and gypsum, and occasionally sandstones. It is found near Whitehaven, in Cumberland, where alabaster is obtained both for ornamental purposes and for the manufacture of plaster of Paris. In Derbyshire its beds yield large quantities of alabaster frequently termed "Derbyshire spar" or "marble," which is much used for decoration of churches, as it is beautifully veined and takes a good polish, quarries of it being worked at Aston and Chellaston near Derby; while at Barlborough, near Chesterfield, the clay is used for brick-making. In Leicestershire alabaster is also obtained near Syston, and sandstone for building in the neighbourhood of Leicester. In Staffordshire we find alabaster at Tutbury, near Burton-on-Trent; and in Notts it occurs in abundance in the neighbourhood of Newark, Orston, and Axholme; while in the same

county the red marl clay is worked for red brick, tiles, and drain-pipes about Nottingham and Beaston. Blue bricks are made from these beds at Nuneaton and Polesworth in Warwickshire, red bricks and tiles near Coventry and Leamington. At Great Malvern, in Worcestershire, it is worked for bricks, tiles, and drain-pipes, and also in some parts of Somerset, as at Farringdon, near Bath; Canton, near Taunton; and Poole, near Wellington. In Cheshire the red marl is largely quarried for sandstone at Ombersley and Hadley, and for burning into lime at Pattingham and Tattenhall.

New Red Sandstone supplies a large amount of building stone in Northumberland, Cumberland, Yorkshire, Lancashire, Cheshire, Derby, and the Midland Counties, as well as in parts of Gloucester, Somerset, and Devon. In Northumberland it is quarried at Deans, near Newcastle; in Cumberland near St. Bees' Head and Whitehaven, as well as in the neighbourhood of Carlisle, for building purposes; flags and landing being obtained at Lazonby. In Yorkshire a sandstone having dark brown quartz grains, with argillo-siliceous cement, is quarried at Os-motherly, near Northallerton, and at Stockton-on-Tees and Cottingham, near York; also at Gatherly Moor, near Richmond, a similar stone is obtained, weighing 136lb. to the foot cube, which has been much used for buildings in Richmond and Darlington; flags and paving-stones are obtained in the south-west of Yorkshire, near Rotherham and Bradford. In Lancashire a reddish-brown pebbly sandstone is quarried in the vicinity of Liverpool, at Ramhill, Eccleston, near St. Helens, and Rainhill; building stone is also obtained at Preston, Kirby, and Barrow-in-Furness. There are numerous quarries of this stone in Cheshire, at Alderley, Birkenhead, Chester, Frodsham, Kelsall, Macclesfield, Malpas, Neston, and Runcorn. In Derby it is worked at Ashby and Weston-on-Trent. In the counties of Stafford and Warwick we find good building stone near Wolverhampton, Cheadle, Brewood, Codsall, Rugeley, Stafford, Tamworth, and Penkridge.

A white sandstone which has been much used in buildings about Shrewsbury is quarried at Belton, near Drayton, in Salop, and also at Bowdley is a similar stone, which is used in buildings at Ludlow and its neighbourhood. At Bishop's Castle a sandstone is worked for local buildings, and at Bridgenorth flagstones are quarried. In Gloucester a good building stone is found near Cheltenham, and a red sandstone is quarried at Wootton, near Garston. At Ashby-de-la-Zouch, in Leicester, and at Warwick, Leamington, and Polesworth, in Lancashire, a freestone is obtained from this formation, and much used in local buildings. Near Bristol a sandstone is obtained at Easton, and a freestone at Clifton, which has been used in the suspension bridge; a shelly limestone is found at Hamhill, near Bridgewater, and there are also stone quarries at Trull and West Leigh, near Taunton. In Devon it is quarried for building stone at Exminster, Heavitree, and Pakcham; and for hearths and flags at Thorverton.

The beds of clay which occur in many parts of the Red Sandstone formation are largely worked in Warwickshire, at Ansley, Chilvers Coton, and Nettlefold, near Nuneaton, for the manufacture of blue bricks and tiles. In Worcester there are brick works at Ordingley, near Droitwich, and fire-bricks are made from it at the Stoke Works; at Malvern it is used for tiles and drain-pipes. In Stafford red and blue bricks, paving and drain-tiles are made at Winsill, near Burton-on-Trent, from this clay. In Cheshire it is worked for ordinary bricks at Runcorn, Stockport, and Wrexham, and for fire-bricks near Macclesfield.

Permian strata, or "Dolomites" underlie the New Red Sandstone geologically, the beds

greatly resembling those of the Trias, with the exception of the magnesian limestone, which is absent in the upper rocks, but is abundant in the lower; their general characteristics being red sandstone and marl, magnesian limestone, marl slate, and conglomerate. They are found near the surface along an almost unbroken line of country, reaching from the mouth of the Tees, in Yorkshire, to that of the Exe, in Devon, with a branch in a north-westerly direction to the mouth of the Mersey. The prevalent red colour in these rocks is indicated by the names of several places in which they abound, as Rotherham, Retford, Radford, Redcliffe, Radstock, &c.

Red sandstone and marl of the Permian series are found westward of Doncaster, also at St. Bees' Head and Corby Castle, in Cumberland, Furness Abbey having been built from the stone quarried at St. Bees' Head. Near Manchester there are beds of red marl, clay and sandstone, with bands of limestone, the thickness being 140ft. In the Lake district these beds attain a thickness of 4,000ft. near Appleby, and of 8,000ft. at Penrith. In Durham there are beds 700ft. thick of marls containing gypsum, beds of limestone, marl slate, and sandstone, at Thiekley, Ferryhill, and Durham, the Lower Red Sandstone being found at Clacksheugh. In Yorkshire the Lower Red Sandstone appears near Knaresborough and Pontefract, in Lancashire at Astley, and in Cumberland at Penrith. It extends westward from Wolverhampton, in Stafford, to Coalbrookdale, in Salop, is found on the south of Shrewsbury and on the borders of the Dudley coal-field. In South Stafford the beds reach a thickness of 3,000, and in North Stafford of 700ft. Beds of sandstone are quarried near the town of Stafford. In Warwick a sandstone for local buildings is obtained at Baxterley, near Atherstone.

Magnesian Limestone or *Dolomite* is the most important feature in the Permian series from the architect's point of view, that material having been selected for the external facing of the Houses of Parliament at Westminster, the Geological Museum in Jernyn-street, and many other important buildings, on account of its uniformity of texture and colour, which render it peculiarly suitable for architectural work. In this country the Dolomite comes to the surface over a very limited area, a narrow strip of it forming the eastern boundary of the Durham and Yorkshire coal-fields. The northernmost outcrop is at Tynemouth, from whence it extends southward along the coast to Hartlepool, and then turns inland towards Bishops Auckland and Darlington. In Yorkshire the Dolomite extends in a narrow belt from Bedale in the north, by Ripon, Knaresborough, Tadcaster, Pontefract, and Doncaster, going southward through Notts, by Worksop and Mansfield, as far as Nottingham.

In Durham the stone is quarried for building purposes at South Shields, Boldon, Fulwell near Sunderland, Trimdon, Coxhoe, Ferryhill, Midridge near Shildon, Aycliffe, and other places. The most important quarries, however, are those which are worked in Yorkshire, Nottingham, and Derby, in the narrow strip cropping out between Tadcaster on the north and Mansfield on the south, where the stone which is found consists, with few exceptions, almost entirely of the carbonates of lime and magnesia. The purest of these is that obtained at Robin Hood's well, near Doncaster, which is of a cream colour, and partly crystalline, its composition being $41\frac{1}{2}$ per cent. of magnesia to $55\frac{1}{2}$ of lime, without any trace of silica. Its weight is 137lb. per cubic foot. The stone found in Roche Abbey, between Rotherham and Bawtry, is of a similar description, having $39\frac{1}{2}$ per cent. of magnesia to $57\frac{1}{2}$ of lime, with less than 1 per cent. of silica, and cubic foot weighs 139lb. It has been much

used in building the churches of that locality. The stone quarried at Anston, between Worksop and Rotherham, has been largely used for building, and together with that of Bolsover-moor in Derby, was employed for the outside of the Houses of Parliament and the Geological Museum. The weight of Anston stone is 144lb., and of Bolsover 151lb. per cubic foot. The composition is very similar in all the stone in this locality, being from $42\frac{1}{2}$ to 45 per cent. of magnesia with from 51 to 53 per cent. of lime, and a small proportion of silica. A similar stone is found at Huddlesstone, near Pontefract, the weight of which is 137lb. per cubic foot. This has been largely used for building purposes in Yorkshire, as at York Minster, Selby Castle, Sherburn Church, and also in London at Westminster Hall, and Henry VIIIth's Chapel. A soft magnesian limestone is obtained at Brodsworth, near Doncaster, which was used in old Doncaster church, but is not durable. Its weight is 133lb. to the cubic foot. The stone of Cadeby, near Doncaster, has also been used in London, but perishes rapidly. Its weight is only 126 $\frac{1}{2}$ lb. to the foot; but at Conisborough, in the same locality, a good and durable stone can be obtained, and was formerly much used in that neighbourhood. The stone found on Bramham Moor, near Tadcaster, at the quarries of Jackdaw Craig and Smawse, has been long used for buildings in that part of Yorkshire, as at the churches of York, Tadcaster, Beverley, Hull, and Ripon. In most cases, however, it shows signs of decay. The weight of these stones is 128lb. to the foot.

In the neighbourhood of Mansfield, Notts, we find a dolomite which contains about 50 per cent. of silica, the lime and magnesia acting as a cement for holding the siliceous particles together. The stone of Mansfield is largely used and much esteemed for architectural purposes on account of its colour, durability, and fineness of texture. The white stone contains only 7 per cent. of magnesia, add weighs 146lb per cubic foot, while the red contains 16 per cent. of magnesia, and weighs 148lb. per cubic foot.

A hard and compact sandstone belonging to this formation is also largely quarried at Elland Edge, near Halifax, chiefly for walling and paving stones. Its weight is 153lb. to the cubic foot. The dolomite found near Castleford, Leeds, Knottingley, Milford, Selby, and many other places, is used for burning into lime.

ART STUDY AND ART WORKERS.

AT the recent annual meeting of the Nottingham School of Art, the head master—Mr. J. S. Rawle, to whose efforts the school owes its present enviable position, gave a very sensible address to the assembled students. He said if

"A thing of beauty is a joy for ever" it should also be a joy for everyone. No student should imagine that the things which specially interested those of different occupations to his were therefore of no interest likewise to himself. What he meant was this, those who were ornamentists should seek all the good, and learn all they possibly could from the pictures, and those who were artist students should not think that ornamental art was beneath their notice. The followers of each branch of art might learn much from each other's work. For there was not that wide gulf between the work of the ornamentists and of the artist which many so erroneously supposed. The same broad principles, the same great truths, should guide both. There was not one art for the designer and another art for the picture maker. In a picture the mode by which the beauty of line and of form were produced was not so evident, for pictorial art should disguise the means by which the end was gained; whereas in an ornamental design they might, without restraint, show more completely those lines and subordinate masses which led up to the principal forms. If they critically analysed a good picture and a good piece of ornamental work they would find that

the same guiding principles, in a greater or a less degree, had influenced the construction of each. And experience proved that the greater the art power possessed by the designer the better would be his work. It was also true that a knowledge of ornamental design would prove a help to the artist. This should always be felt, and then, although pictorial art was, of course, the higher development, there would be a greater bond of sympathy between the two, which would prove of benefit to both. Ornamental art should be considered as the younger sister to pictorial art, and not be, as was often the case, banished out of the family altogether, as something unworthy of association. This union would not degrade the latter, but would certainly elevate and ennoble the former. The workers in each branch of art should remember that all good original work must be based upon what had gone before. If it were not for the influence of the past upon them they would be in the condition of a New Zealander, who, without a history to build his experience upon, could only carry his primitive art-power as far as the carving of rude simple forms upon the prow of his canoe. If they looked back upon the past epochs of art, both ornamental and pictorial, they found, in every case, that there had been a gradual growth which in time only, through a succession of workers, had brought about some distinctive characteristic which marked the art-history of the period. A style in art was never originated solely by one man, but by the united efforts of a succession of men working together with one aim, each taking the excellences, or the peculiarities, of his predecessors as a foundation upon which to build a more complete superstructure. It was difficult sometimes for these who were actually working to note the gradual change that was taking place. It was only by looking back that they were able to mark progress, or the reverse, for art had its periods of decadence as well as its periods of advancement. Future generations would be better able to understand and to appreciate, at its true value, the work that was being done in this the Victorian Age. They might see, by looking back some fifty years, what a great, he felt he might justly say,—what a mighty change had come over the art-practice and general art-feeling in this country, in that period of time. It matters not whether they looked at pictorial or at decorative art. The art of to-day was a different thing to what it was half a century ago. Who was there who would say that ornamental design had not, with them, made gigantic strides in this period of time? Indeed they might only step back a quarter of a century, and see what their own curtains were like then,—when straggling palm trees, with birds and beasts, unknown to natural history, did duty for ornament; when lions or panthers sprawled upon their hearth-rugs, and when patterns, outrageous in form and in colour, disfigured their walls. Let them be thankful that they knew better now. There was now a greater sense of propriety and fitness in construction which guided all their decorative work. There was better form and better colour. And let them rejoice when they knew that they could do this better work themselves, without having to place an ignoble dependence upon outside foreign help. And again, with regard to the Fine Arts; many pictures of fifty years ago, which were then thought worthy of honoured places in the rooms of the Royal Academy would now be rejected from a second or third-rate provincial exhibition. It was doubtful whether they could mark much increase in the number of great men, for genius was a Divine gift which shone out but rarely, and appeared only as God, in his good time, pleased to bless the world with it. Genius might be helped by favourable conditions—it could never be created. The great changes in the past half-century were more to be observed in the rank and file of art-workers. Where there was one man who, fifty years ago, could paint a fairly good picture they found now a score of men and of women who could do far better. There was now a casting aside of worn-out academic rules and mannerisms, and a more direct study of Nature. She became the true source of inspiration—the trammels of formal rules and traditions had been burst asunder, and Nature's laws had come to be considered first, and the canons of Art, afterwards. They saw on all sides more truth and vitality, although they could not shut their eyes to the fact that there were tendencies to be observed, here and there, to run into wrong

grooves which must be watched and guarded against. Art was, comparatively, of recent growth in this country. It had shown its widespread influence in other nations long before it even began to take root in British soil. They could hardly go so far back as Holbein or Vandyck, and say that these men were exponents of English Art, for they were foreigners who came to live with them, importing some of that art-power which, unfortunately, the English did not then possess. It was not until the middle of the last century, that England commenced to show the world that she also could have an art-life of her own; and it was Hogarth, Gainsborough, and, more particularly Reynolds, who may be said to have given birth to the English School of Painting. They burst forth like meteors, out of great darkness, and produced works which were the admiration of all men, and which would stand the test of all time. With them a brighter era dawned; and soon arose the genius of Wilkie, of Etty, and of Müller, to assert that art should indeed have an abiding home in this land. But, perhaps the most wonderful development of all has been the rise and the progress of the English School of Landscape Painting. England stood proudly alone, on an eminence as the birthplace of the modern school of landscape painting. Whatever might be their failings in other branches of art no one would dare to snatch from them the honour of having won unparalleled success in the representation of all that was beautiful and grand in the world of nature surrounding them. It was only in the beginning of the present century that a constellation of geniuses made its appearance, and the works of Constable, Patrick Nasmyth, De Wint, Copley Fielding, David Cox, and Turner, showed the whole world the glories of the meadow, the river-bank, and the mountain side. These men, together with the figure painters before mentioned, had testified to their fellow-men that art, with all its beauty of form and glow of colour, could live in their midst, and take a deep hold of their hearts and minds, notwithstanding their cloudy skies and choking fogs. They must not join, then, with those who so unjustly said that the English were not, and could not, possibly be an artistic nation. (Applause.) They must remember how young their national art-life was, and not close their eyes, wilfully, to the fact, that each decade of years showed signs of an increasing, and of an enduring strength. But, if a yet more glorious future was to be unfolded for them, they must all remember that the humblest workers in the cause of art had their fair and just share of work to do. It was not to the great alone that they must look, but also to the small from whom the great must spring. Those who were students should remember that, insignificant though their powers might then be, they were still part and parcel of the great company of art-workers. They, too, could help towards whatever greatness and glory in art their country had in store for them. They could do this by deeply loving their work—by throwing their whole soul and mind into it with the determination ever uppermost before them—that whatever they had to do must be done honestly and thoroughly, and with a reverent spirit.

PICTURES AND ETCHINGS.

MESSRS. ELLIOTT & FRY, of Baker-street, the well-known photographic artists, have just opened an exhibition of paintings well worth a visit. The works exhibited are chiefly those of an artist who must be acknowledged as one of the most gifted painters we have—we mean Mr. Hubert Herkomer. For power of imagination, and for the faculty of rendering character, few modern artists are his equal; but the most remarkable peculiarity impressed upon us by these works is that Mr. Herkomer can paint both grand and small subjects. He can cover a canvas nearly as large as any Raphael or Rubens ever painted upon, with subjects of surpassing breadth and depth of tone; and he can paint, with exquisite feeling and minuteness of detail, *genre* pictures of cabinet delicacy. We are struck, on looking over the collection of Messrs. Elliott and Fry, with Mr. Herkomer's now almost historical picture, "The Last Muster," made known to the public by the beautiful steel engravings. For accurate drawing and vigour of handling, no less than for *chiaroscuro* and colour, this is one of the finest studies of the

painter. "Rest" is the artist's title for a water-colour representing as a scene Aldenham Church-yard, near Watford. At a second glance we catch the meaning of the designation. An old, wrinkled woman of the allotted span of life, such as the artist alone can depict with such a forcible expression of countenance, is seated under a tree absorbed in meditation and enjoying the quiet and rest of the churchyard. This is certainly executed in the happiest style of the artist. The time-stained church and the exquisite portrayal of the lineaments of the face of the old woman unite to place the picture above the ordinary run of representative subjects. Mr. Herkomer, though he often verges on the "grand" style, does not indulge in ideal portraiture; his countenances are all essentially natural, though never vulgar or trivial. Thus his picture called "Bittgang," a pleasing incident founded on a religious custom of blessing the crops in Bavaria; his study of Mr. Fry's gardener, together with "A Word of Advice," one of his recent productions, "A Souvenir of Rembrandt," and his fine picture, entitled "Who Comes Here?" are marvels of expression. A striking study in water-colours depicts the shooting of a poacher, an episode of hunting life in the Black Forest, which Mr. Herkomer has illustrated with dramatic effect. The picture is small, but the figures, the horror depicted in the countenances of the gamekeeper and hunting party, and the half-revealed fact of the fatal shot in the discovery of the dead man, whose legs only appear in the foreground, render this a wonderful instance of the artist's power in narrating plot. The sequel to this story, called the "Arrest," is perhaps still more clever as a study of countenance and of character. Another incident in the Black Forest, under the name of "A Dilemma," has been wonderfully told by the artist. A tourist and his wife, a newly-married couple, have lost their way, and enter the room of a chalet, in which a group of people sit. The stranger, guide-book in hand, endeavours to make himself understood, but the faces of the bewildered occupants tell too clearly that they are not understood by any, while the faces of a few others betray suspicion of the intruders. Equally telling is another piece in which two women are engaged in gossip. We cannot mistake the air of the two interlocutors, whose very countenances seem bent on tittle-tattle. A long piece, showing a forest of pine with wood-cutters, is perhaps one of the most masterly and finished in this collection, and we believe the artist himself thinks it one of his happiest works. The tree stems are truthful, and the colouring has a depth of tone thoroughly characteristic. In *genre* subjects Mr. Herkomer seems to excel, and we saw a few groups of studies, and figures painted with an exquisite feeling, with an oil-like body of colour. This *impasto* mode of execution seems to be a favourite one, particularly in some of the earlier pieces. The artist works his figures up with a thick body of colour, upon which the lights are placed in opaque pigments. As a masterpiece of grouping and colour, "Who Comes Here," occupies a high place in the collection. The old man's and the little girl's faces eager to know who the stranger is, are marvellous in their truth, expression, and execution. We must not omit to notice some very clever allegorical subjects. One, a "Fairy Symphony," is a composition of a highly poetic kind in which the artist has drawn largely upon his imagination. In this instance there is a wealth of imagery in the sylphs and monsters introduced, and the semi-spectral treatment is very clever. The composition is founded apparently on a mythological legend. The artist's "Fawn Fancies," and symbolic studies of "Morning" and "Evening" are also clever and highly decorative. Those who wish to see some of Mr. Herkomer's choicest works cannot do better than to pay a visit to the collection of Messrs. Elliott and Fry.

Messrs. J. Hogarth and Sons, of Mount-street, Grosvenor-square, have on view a collection of etchings, by Messrs. C. P. and F. Slocombe, of a character that will repay inspection. They chiefly comprise views executed from nature. Those by Mr. C. P. Slocombe represent coast scenery in Cornwall, and other parts, and display a thoroughly artistic conception. In rock scenery, as well as in foliage, Mr. Slocombe is particularly happy, and we may point to "Path through the pine wood," "Chalk cliffs and boulders, Rottingdean, Sussex," "King Arthur's Castle, Tintagel, Cornwall," and "Lyndhurst, New Forest," as particularly expressive pieces in

which the artist's needle has depicted with a great deal of feeling and colour these objects. "Stonehenge, mid-day," is a fine etching, and Mr. Slocombe's handling seems well suited for the exhibition of the rocky and rugged elements of the picturesque. "Pembroke Castle, South Wales," and "Moonlight" in Surrey, show the artist's capability in two branches of delineation. The latter is a fine vista through a pine wood executed in a vigorous style, though the clouds are rather black. "A quiet retreat, Pinner, Middlesex," admirably expresses the character of its title. The old house, surrounded by some lofty trees of birch and poplar, is cleverly rendered. In the etching "At Lyndhurst," the cottage by the roadside, the foliage, and especially the oak in the foreground, are very truthful in drawing, and there is a soft chalk effect in the etching of the foliage. We note also one or two architectural subjects, "Rue du Roi Priant, Rouen," a picturesque sketch, and a "Street in Rouen," with some old gabled timber houses. The portraits called "Captain of a Pilchard Boat, St. Ives," is a cleverly executed study of expression; the mouth and the pipe are exceedingly natural. Many of these etchings are in brown ink. Mr. F. Slocombe has a very different manner from that of his brother. There is a clearer and more decided execution, but we lose some of the softer effects. "Steephill Cave," "Isle of Wight," "Margate Harbour," and "Jetty," and "Colliers unloading, Margate," are all very cleverly drawn. There is a breadth of treatment, and a great deal of colour in the etching. "A Girl in the Costume of the latter part of the 16th Century" shows some skilful drawing and *chiaroscuro*. We only add here that these etchings can be purchased separately or mounted in portfolios, at 60 and 18 guineas respectively for each series.

A LOAN COLLECTION OF WORKS OF JOSIAH WEDGWOOD.

THE Liverpool Art Club have on view a fine collection of works by that incomparable potter Wedgwood, arranged as they are set out in his own catalogue. The promoters have been assisted by Messrs. Wedgwood in this task, and it is no exaggeration to say the series of works brought together has never been surpassed. As usual, the catalogue before us gives the visitor every information he can require. The marks on Wedgwood ware are made the subject of a chapter. Of these we find it stated "the marks of the good period are usually clearly and evenly stamped, and except upon glazed pottery and Queen's ware, easily deciphered. With the name is often found either single letters, numbers, or signs, scratched or impressed." Many of these are only workmen's marks. A rude K made with a point is found upon some of the fine busts attributed to Keeling. Various stamps are illustrated which will be a useful guide; but many genuine pieces of old Wedgwood are found unmarked. The introduction gives a sketch of the artist's history, from which we learn he was apprenticed to his eldest brother in 1744, and in 1752 commenced at the Bank Pottery, Stoke, in partnership with Messrs. Harrison and Alders. Pottery was at that time in a low state in Staffordshire, and Wedgwood helped to convert it into an elegant art. The manuscripts referred to give some interesting particulars. It may here be mentioned that Wedgwood was not an original artist. His Portland vase, so justly admired, was a copy, and his works were generally imitations of Classic conceptions. His cameos are accurate reproductions from antique gems and models. His copies from Romano-Egyptian gems are various. There is one, a figure of Apis, with a winged disc, and an emblem of the soul in cream-coloured biscuit porcelain 9-16 in. by 3 in. "A Figure of Osiris," various figures, &c., from Gnostic amulets. Classical subjects, some upon cream-coloured porcelain, others upon jasper ware, from gems are numerous: these vary from 1/2 an inch wide to 2 in. or more square. Portraits are common, often upon white jasper ware body with blue ground. Over a hundred cameos are mentioned. We may observe that the jasper ware surpasses for fineness and durability any other; and the most minute touches could be made upon it. The next section refers to the intaglios; these were also chiefly from antique gems. Most of these are in black basalt ware, oval in shape, and the average size about 3/4 in. and 1/2 in. They are impressed "Wedgwood and Bentley."

Some of these are executed for ornamental purposes, such as box-tops, watch backs, &c. Class II. contains a valuable collection of bas-reliefs, medallions, &c. They are chiefly in jasper of two colours, pale blue being a common colour, and are applied to cabinets, chimney-pieces, and other furniture. The subjects are largely chosen from Classical stories. We note No. 542, "Marriage of Cupid and Psyche," enlarged from a celebrated cinquecento gem, oval in form; also 538, 525, 585, Head of Medusa, modelled by Flaxman, circular in shape, the workmanship exquisite, and the colour blue body, head in white relief. Some of these are over a foot in length. Many are moulded from cinquecento works. One of the most interesting divisions of the exhibition is that containing portraits of illustrious persons of Greece, Egypt, and of Roman and European celebrity. These portraits are in basalt and jasper on coloured grounds, and their usual size is 2in. by 1½in. A regular series divided into kings and queens, statesmen, philosophers, and poets is catalogued. Most of the medals are double. The Roman history medals begin with Romulus to the end of the Consular Government, and include a series of 60 in number. The medals have cameos on both sides, thus the head of Romulus has a reverse, "Foundation of Rome"; the Rape of Sabine has on reverse, "Peace procured by Sabine." Heads of illustrious Romans, the Twelve Cæsars and their Emperors, heads of Popes (258 in number taken from Dasser medals) in basalt ware, heads of illustrious moderns are among the collection. The last group is the most interesting; they are in black basalt, or blue and white jasper, chiefly the latter, and generally oval. The catalogue contains a full description of each. The portraits have been modelled in some cases from life by modellers employed by Wedgwood; in the majority of cases, however, they are from medals, waxes, and engravings. These heads have often grounds of dark blue, reddish brown, and black. The groups of busts, vases, lamps, statues, &c., are also particularly interesting examples, and exhibit the versatility of the works of this master. The catalogue is a masterly work of the kind, and has been compiled by Mr. Charles T. Gatty.

CINGALESE ART REMAINS.

SOME explorations have been recently conducted in Ceylon on the site of the ancient capital of the Cingalese Kings Anuradapura, now in ruins. One Dagoba called the Thuparama, which has been uncovered must have been a magnificent structure in its perfect state. This building is supposed to enshrine the left collar bone of Buddha (some say the left jaw bone); but these relics were always deposited in golden caskets, beautified with profuse settings of gems of great value, before they were enshrined in the edifices erected for their reception. The Thuparama stands on a circular platform, the brick walls supporting it are of great thickness, and on the outside embellished with fine mouldings and pilasters of the same materials, though there can be no doubt that the whole of the outside, including the parapet which once encircled it, was originally covered with plaster, and possibly, too, decorated with paintings. This platform is paved with slabs of granite. On this platform are four concentric rows of graceful octagonal columns. The first row is close to the base of the Dagoba, the second row about 2ft. from the first, the third about 5ft. from the second, and the fourth row, the columns and capitals of which are carved from a single stone, is arranged round the margin of the platform. The capitals of the first two rows are ornamented along their upper edge with grotesque squatting figures, with arms upraised, as though supporting a weight resting on their heads; the third row has eagles standing upright with outstretched wings; and the fourth or outer row is ornamented in a similar manner with quaint dwarfed figures in every conceivable position. The tops of all the columns below the capitals, which are also octagonal, are ornamented with a fringe and tassels of very graceful design, those on the outer columns being of a very different pattern from those on the three inner rows. The height of the inner row of columns is 2ft., the second 22ft., the third 19ft., and the outer row (all monoliths) 14ft. Between the third and fourth

rows of columns there was evidently a wall, no longer in existence, the stone foundation of which, slightly raised above the rest of the pavement, can be very easily traced. The rows of columns round the Dagoba are arranged in quadrants so as to form a rather broad passage to each of the cardinal points of the Dagoba, where there was probably an altar close to its base. At the east and west sides of the building are fine sets of stone stairs reaching to the platform, 14ft. above the ground, the steps having been ornamented with carved stones, and wing walls, now thrown down, which were finished off with flat stone slabs richly carved with figures bearing bowls or vases containing the sacred lotus flowers. These carved stone slabs still remain in position, but some are broken. Opposite the landing of these steps, and in a line with the foundation of the circular wall which is supposed to have once encircled the Dagoba, will be found a double step carved out of one block of stone and mortised above to receive the stone door frame, which once formed the entrance, and this goes further to favour the supposition of a wall having previously existed. The object of these beautiful stone pillars and wall was undoubtedly to sustain a magnificent conical roof, which would have covered the whole of the Dagoba. The interior of this roof, the Dagoba, columns, walls both inside and out, altars, and, in fact, everything about the building must have originally been most gorgeously painted. That it was so is pretty clearly proved by the recent excavations most carefully made both here and in other places, where thin coatings of very fine plaster are found covering the stone and brickwork, with traces of bright colours. At the Ruamveli Dagoba some fine paintings have been brought to light. The height of the Thuparama is 62½ft. from the pavement at its base, the diameter of the base 59ft., and the lower part of the plain bell, 33ft.

HOUSEHOLD SANITARY ARRANGEMENTS.

THE first of a course of six Cantor lectures on "Dwelling Houses: their Sanitary Construction and Arrangements" was delivered by Dr. W. H. Corfield, M.A., Professor of Hygiene at University College, at the Society of Arts on Monday evening. A number of specimens from the Parkes Museum of Hygiene were exhibited in illustration of the lecture. Where choice of situation was at all possible, the "exposition" of a house was of importance; a house facing east would be exposed to cold and dry winds, and facing south-west to driving rain. More important than this was the character of the soil beneath a house. Soils were divisible into two classes, those pervious and those impervious to water. Typical of the former class were gravels and sands; then came loose limestones and sandstones, and other rocks through the masses of which water could percolate; chalks, and the limestones and granites so freely fissured that water could easily escape. In the other class were the clays and marls. Each class of soil was under certain conditions dangerous to the life of those living in houses built upon it; the dwellers upon impervious soils were liable to consumption and rheumatism, those on pervious soils to typhoid fever and to cholera and other epidemics when those had obtained entrance into the district. In this choice of evils there might at first seem little preference, but this was not the case. The dangers of pervious soils were not only less fatal, but could be more easily coped with, and chiefly by lowering the sub-soil water, so that it did not approach the level of the foundations of the dwellings. Towns were often built in basins of pervious soils resting on impervious ones, and these basins were sometimes waterlogged to a considerable extent. In such towns, whenever this ground water had been lowered by drainage the deaths from consumption had decreased. Specimens of agricultural drain pipes were exhibited, and it was shown that drains, unlike sewers, ought to be but loosely jointed and laid with regular fall. Passing on to notice the foundations of houses, the dangers of "made earth" were indicated. Such sites ought not to be built upon for a considerable time, for it had been shown by Drs. Parkes and Burdon Sanderson that the organic matters in them slowly became innocuous by subterranean oxidation, and they should then be covered by a layer of concrete,

not only upon the entire surface to be occupied by the house, but also for a considerable distance beyond. The materials of foundations ought to be, for sanitary, as well as constructional reasons, exceptionally good, but as a rule they were the worst used in the fabric. The surface of the basement should be covered with water-proof and air-proof material. One mode of doing this was by Pritchard's patent flooring, which consisted of a series of agricultural tiles laid side by side, upon them being a layer of concrete, which could either be left plain or faced with asphalt or tiling. No wooden floors should be laid in basements, which ought not to be used for other than cellarage purposes, and certainly not as sleeping apartments. Just above the ground level a damp course of any impervious material should be laid all round the house; for this purpose cement should not be used on account of its liability to crack. Another misapplication of cement was sometimes seen on brick houses built on damp sites; in these, unless precautions were taken, the subsoil water often rose by capillary attraction, and to render the house less damp, the walls were frequently plastered with cement. The consequence was that the water which had evaporated on both surfaces of the walls could now but escape into the rooms, and thus the remedy was worse than the disease. Dry areas, well drained, should be provided outside the houses. For walls the most fireproof material was brick, and next it concrete, for both had already been burnt. Where walls were exposed to much rain they should be protected either by being faced with glazed bricks or hung with tiles or slates, and, if of brick, it was wise to build them hollow. Chimney flues should be as straight as possible, kept separate from each other, and where practicable, lined with pipes to facilitate cleansing and reduce the danger of spread of fire. It was desirable floors should be fireproof; if of timber the boarding ought to be so laid and pugged as to prevent the passage of air from the rooms below. It was essential to durability that the space between floor and ceiling should be ventilated by external gratings or otherwise. A new method of ventilating rooms and floor-joists, now under trial, for which some advantages were claimed, was known as Ellison's patent conical ventilator. It consisted of bricks pierced in couples, with cone-shaped apertures, the small hole being placed outwardly and communicating with the interior of the house by a broad shallow hollow. It was claimed that heat and air would enter by the small hole, and would be so reduced in velocity that its entry into a room would cause no perceptible draught. In roof construction it was desirable that no cornices or eaves' details should drip upon the walls of house. Gutters behind parapets ought to be wide enough to allow a man to stand in them, and means should exist for facilitating the removal of snow; if allowed to accumulate it slowly melted and would find its way through the roof. The point that all rain-water pipes should be kept outside the house was insisted upon. The lecturer had traced many cases of diphtheria and other illnesses to the bringing or rain-pipes through rooms from the front to back of houses, &c. Bits of leaves and rubbish fell into these pipes in spite of wire guards, and there decomposed. Another common danger was the opening of pipes below bedroom windows. Floors were best polished and bees'-waxed, or laid with parquetry—plans adopted in the best hospitals, where cleanliness was a primary necessity. Skirting boards should be let into grooves, to prevent dust accumulations and draughts resulting from subsequent shrinkage. If carpets were used a space should be left all round to facilitate frequent and easy cleansing. The best wall covering was tiles, if well laid; if plastered, it was much better painted. Wall papers were open to grave objections: they harboured dust and disease-germs, could not be thoroughly cleansed, and frequently their colours contained arsenic, more especially the green and brown shades—a cause of much unsuspected suffering. For these reasons ceilings should not be papered; if of wood they should be panelled. All wood-work should, as far as possible, be polished, stained and varnished, or painted.

The President of the Royal Institute of British Architects has received a compliment from Austria. Mr. Charles Barry has been elected an Honorary Member of the Imperial and Royal Academy of Fine Arts of Vienna.

ARCHITECTURAL ASSOCIATION.

THE fortnightly meeting of the Association was held on Friday evening; the President, Mr. H. L. Florence in the chair. The following new members were elected:—C. C. Bradley, A. Nixon, F. Littlewood, W. Pope, Christopher E. Rondell, and E. A. Woodrow. A vote of thanks was passed to Mr. Bentley, the architect of St. Mary's R.C. Church, Cadogan-street, for permitting the members of the Association to visit that edifice, and it was announced that the next visit would take place on Saturday, the 22nd inst., at 3 p.m., and would be made to Alexandra-mansions and Members'-buildings, Victoria-street.

THE INTERNATIONAL CONGRESS OF ARCHITECTS AT PARIS.

Mr. R. PHÉNE SPIERS read a paper descriptive of the proceedings at this Congress, which he attended as delegate from the Architectural Association. The Congress was, he explained, organised by the Société Centrale des Architectes, an organisation corresponding roughly to our Institute, but with a membership of 330, and in communication with 15 provincial and 12 foreign societies, of which the Institute is one. Delegates were sent from most of these societies, and over 450 architects from all parts of France and foreign parts signed their names as attending the Congress. The general meetings were held in the Palace of the Trocadero, and the sectional meetings in some of the unoccupied bureaux in the Tuileries. The first meeting took place at the Trocadero on Monday, July 29th, under the presidency of M. Lefuel, architect of the modern parts of the Louvre and the Tuileries, when M. Hermant read a paper "*L'Esthétique à la portée de tout le monde*" (*Esthetics placed within the reach of Everyone, or Esthetics for the Million*), the purport being that Art is regulated by certain definite principles and laws, which ought to be laid down and determined in the same way as those of science. For an object to be beautiful it must conform, he argued, to the usual type of its class, as a whole and in all its details and proportions. The argument should have been carried a step further, but M. Hermant disclaimed any intention of himself laying down the laws governing esthetics, and simply introduced the subject. Unfortunately, as no discussion was allowed at the meetings, the subject dropped at its birth. On Tuesday a paper was read by M. Courau on "*The Education and Professional Status of the Architect*," in which he set forth the invasion of the architect's province of work by the engineer, placing the former in a very precarious position, especially in the provinces. Persons without any architectural instruction, he said, uneducated though acquainted with the customs and a few of the technical terms used in building, assume the title of architect, and either by unscrupulous conduct or ignorance bring discredit on the whole profession. As a remedy for this, M. Courau advocated the establishment of a diploma, which would require from the average run of architects such a course of study as would be a guarantee to the public, and eventually raise the standard of the profession. The idea of the institution of a diploma originated, he reminded members, with the Société Centrale, and might well be taken up again and brought to a definite solution. M. Gueset warmly urged the Congress to take steps to prevent the taking of illicit commissions, which more than anything else was bringing the profession into discredit. Mr. R. Phéne Spiers gave a description of the architectural examination organised by the R.I.B.A. in 1862, and deplored the fact that owing to the apathy of the committee, especially during the last few years, the scheme had well nigh fallen through. Señor Bohinas, secretary of the Central Society of Architects in Madrid, informed the Congress that in Spain the obtaining of the diploma was a necessity for those practising as architects. There was a school of architecture in Madrid, three years being the usual period of study, at the end of which an examination was held, which might be gone through by those who came up from the country or preferred private study to that of the school. Four years had then to be passed in an architect's office and on works in progress, after which a second examination had to be passed, which confirmed the diploma. Herr Klein, the delegate from Copenhagen, stated that there was a diploma in Denmark, but not compulsory; thus there were two classes of architects—those

who had obtained the diploma, and those who had not. Some of the diplomaed architects were men of very little ability, and some of the other class of considerable talent, so that he did not consider the diploma was of any value. M. Jean Strohman, councillor of state, professor of architecture, and master of the Imperial Academy of Fine Arts in St. Petersburg, spoke of the unsatisfactory position of the architect in Russia, and advocated a diploma. It was intended to return to the subject on the following day; but there being no time set apart for it, it dropped. M. Dutert then read a paper on the architectural designs exhibited in the Salon of 1878, and Mr. R. P. Spiers gave, by desire, a description of the career of an architectural student in England, and an account of the condition of architecture in that country. General surprise was excited that the system of pupilage yet prevailed in this country, and the statement that premiums of from 100 to 200 guineas were frequently paid to secure admission into an architect's office created amusement. In the afternoon, another meeting was held, at which M. Davioud read an essay, "*On the Union or the Separation of the Architect and the Engineer*," which had gained a prize from the Académie des Beaux Arts. The author divided his subject into four parts:—1st, What is the State Engineer? 2nd, What is the Civil Engineer? 3rd, What is the Architect? and, 4th, What are the actual relations between engineers and architects, and what should be done to improve them? In answering the first question, M. Davioud described in detail the organisation of the Corps des Ponts et Chaussées, distinguishing between the mining engineer, the engineer who formed part of the service of bridges and highways, and the military engineer. He contended that centralisation and subordination of one to another had suppressed the initiative of the individual, and consequently all originality and artistic feeling was lost. The State engineer had his life so marked out and defined that he is unable to free himself from the trammels imposed on him, and eventually becomes a mere wheel in the great machine which constitutes the French Board of Works. He considered that the course of study pursued by the State engineer in the Ecole Polytechnique is too theoretical and abstract, and its tendency is to form a body of men who do not draw or even make calculations, but prefer to alter, correct, and sign what is submitted to them, and to make work for the engineers, inspectors, and architects placed under them. Many, however, of the most eminent engineers connected with the French railroads have left the State service to design and carry out the roads, bridges, and machinery of railway companies. In answer to the second question, it was shown that the civil engineer is free and independent. The course of education he has gone through at the Ecole Centrale des Arts et Manufactures is of a more practical kind. The student has to go through a course of construction which might be turned to account in architectural design. Leaving the Ecole Centrale with his diploma, the civil engineer goes into the works as a subordinate, which enables him to study and ask questions without compromising his dignity. Employed in private interests, he is obliged to work hard to acquire his position, and to display a considerable personal value before he can reach the post of chief engineer. M. Davioud does not consider that the civil engineer has done much harm to architecture. He has raised construction to the height of an experimental science, and he has allowed France to rival England by a judicious and economical employment of materials. The civil engineers in France are increasing in number and in public esteem, because they are forced to work, and not allowed to sleep in the enervating atmosphere of "functionarianism." It is to be regretted that they are not artistic. M. Davioud thinks, however, that art is again asserting itself in connection with scientific construction, and foresees the time when the metallurgist, the savant, the ironfounder, and the architect, working together, will produce features of unknown beauty, causing a revolution in art as great as that which took place when Arcuated took the place of Trabeated architecture. In answering the third question, M. Davioud discussed the reasonableness of the law in allowing anyone who chose to call himself an architect. He declared himself a partisan of complete liberty, and considered it was for the client to find out how to obtain capable and fit persons to work for him. As yet, he considered that architects

had never taken sufficient trouble to enlighten the public on the value of the men of merit in the profession, and the equality of salary which they have adopted (by a fixed scale of charges) is not likely to make people believe there is much difference in the merit or talent of those who practise. He classed the 4,000 architects of France into three categories—1st, those who are veritable artists, of whose talent and knowledge there is no question; 2nd, those who have desired to place themselves in the first category, but whose qualifications have not risen to the standard, who nevertheless have become practical architects with business-like qualities; and 3rd, the "usurpers"—men who have gone through no serious course of study, but who have picked up such a superficial knowledge as enables them to compete with talent, and who demand 5 per cent. or even less if they can get it. The weak and enervated individualism of architects was contrasted with the spirit and energy of the civil engineers with their magnificent meeting hall in the rue de Faubourg Poissonnière. Passing on to architectural education, the great improvements made in the Ecole des Beaux Arts were recognised, but it was contended that there is still much room for reform. He believed that the various studies required of the young architect would invigorate him and prevent his becoming a mere decorator or designer on paper. If they compared the work done by the State or civil engineer in the same time as that of the architectural student they must be convinced that if a struggle ever took place between the two professions the architect must go to the wall. In examining the fourth question, the union of architects and engineers, M. Davioud considered architects have obtained most valuable information from the civil engineers on all questions connected with the science of building; any union with the State engineer would, however, he thought, be fatal to the profession. Architects had been called in by the State engineer for public service with disastrous results to the credit of their profession. Already it is a question of establishing a staff of municipal and provincial architects, under which system he contended the architect's art would be lost and he would become a simple functionary. From the civil engineer, however, the architect has nothing to fear but simple rivalry, and a union between those professions was recommended. This essay occupied three sittings, but was followed by no discussion. On Wednesday two sectional meetings were held, the first subject being the scale of charges. M. St. Ginest, President of the Toulouse Architectural Society, urged the importance of drawing up some definite scale of charges applicable to all France, and mentioned that at Marseilles the German sliding-scale had been accepted. The latter system was condemned by M. Ravon, who said any scale should be perfectly clear to both contracting parties; the five classes of building in the German scale would lead to endless disputes and litigation. The subject was again taken up on Friday, when Mr. Spiers described in detail the English system, including the positions held by quantity surveyors and clerks of works; the latter were totally unknown to French architects. On Saturday the matter was again considered, when M. Davioud urged that until there was a compulsory diploma, there ought to be no fixed scale of charges, or the artist would be in the same category as the first comer who might choose to call himself an architect. M. Lucas pleaded that it would be a very difficult and delicate task, to determine the artistic merits of the various members of the profession. A resolution was brought forward by M. Davioud, to the effect that the congress considered that "each architect has the right to adjust the value of his services, according to his own estimate of what would be a just recompense for his talent." There were many dissentients from this mode of leaving the question open, and ultimately it was carried with an addition, stipulating, that in the absence of any preliminary arrangements, the scale of charges fixed by the Council of Public Buildings in 1803 might be accepted as a minimum. That scale was: for drawings of every kind 1½ per cent.; superintendence of work 1½ per cent.; quantities and specifications, 2 per cent.; total 5 per cent.; but besides this a French architect charges a fee of from 6 to 8 frs. for arbitration, and 1 fr. per mile travelling expenses. Returning to the Wednesday meeting in the second section, the education of working men was there taken up, and M. Lucas read a paper advocating the establishment of a technical school of apprentice-

ship for workmen of all classes, instead of the present system, by which they pick up their information as best they can. In the afternoon M. Trelat, Director of the Ecole Centrale d'Architecture, delivered an eloquent address, in which he contrasted the aim of the architect with that of the engineer. The architect has three conditions to fulfil: to distribute, to form, and to construct. When we examine these conditions, we see the great difficulties with which he has to contend, for these are absolutely contradictory to one another. When the plans, elevations, and sections have been distributed in accordance with the conditions required, then the artistic element has to be considered, and various changes made to bring both into accord. Both may require further alteration and modification to bring them in accordance with structural necessities. We see buildings admirably constructed, as far as stability, economy, and excellence of materials go; but they are incompatible with architectural beauty; they have neither style nor expression. The engineer can plan and calculate the strength of materials; the contractor can build: it is the architect's mission to unite the two with beauty and expression. To do this he must sometimes sacrifice a part of his art; but if he allows the unity of his design to be sacrificed he abandons his special characteristic. The engineer is young—he dates only from the 17th century, but he is at present the conqueror. He has only two conditions to fulfil—to distribute and to construct; with form and unity he does not concern himself. The education he requires is quite different from that which the architect should possess. M. Trelat advised architects to take up those special studies for which his school was established. There, he said, he insisted on a better groundwork of knowledge of the sciences, and of the theory and practice of the economy of construction. There was a large staff of professors, and periodical examinations held. After three years here most of the students proceeded to the Ecole des Beaux Arts, to acquire proficiency in artistic design.

(To be Continued.)

ROYAL ACADEMY LECTURES ON ARCHITECTURE.

ITALIAN GOTHIC IN SECULAR BUILDINGS.

PROFESSOR BARRY devoted his third Academy lecture to the consideration of how Pointed architecture was applied by the architects of Northern Italy to secular buildings. The period of the Renaissance under consideration was, he observed, a time of transition from ecclesiastical to civil policy; under the influence of democratic ideas, the principal Italian cities vied with each other in erecting noble civic buildings. The town hall generally asserted the importance of the rulers, and was dignified in its architecture, and marked by a characteristic campanile, the symbol of power and independence. But these Italian Gothic campaniles must, he considered, be deemed rather interesting than admirable, in an architectural sense. Rising straight from the ground without buttresses or breaks, usually plain and destitute alike of ornament and of light and shade, a well-designed upper story was but a poor compensation for so much effort exerted for so small a result. The general characteristics of designs for civic buildings did not materially differ from those of other Italian Gothic work, but the horizontal principle was more marked, and the approach to Classicism somewhat nearer than in ecclesiastical examples. A free use of the pointed arch was balanced by the absence of vertical piers or buttresses, and by the strongly marked horizontalism of string and cornice. The latter feature is, indeed, specially suggestive of a Classic origin. It was composed of groups of mouldings, of moderate size and prominence, suitable to construction in brick, the material mostly used. Enrichments of regular forms, not always beautiful in themselves, were arranged in horizontal bands of ornament, and below small arches, either machicolated or intersecting each other. In Venice the erection of the Ducal Palace formed an epoch in Gothic art. In it we find the same half-application of Gothic principles which mark Italian Gothic. Perhaps the most striking feature is the thick and massive tracery. It is strong enough to serve as a constructive feature supporting the fabric above. It is indeed a beam of marble, perforated with quatrefoil openings, laid upon numerous supports, to

which it communicates the strain of support. To counteract the opening thrust upon the joints of masonry, iron tie-rods have in many cases been added from capital to capital. The arcades of the Ducal Palace are very beautiful, and afford a remarkable lesson as to the disposition of light and shadow. Assuming the propriety of the conception, and taking the quatrefoils of the tracery as forming a level band of enrichment, no sculpture, in such a position, would produce the effect of these simple forms, with square edges, displaying themselves in clear-cut prominence against the shadow behind them. In the other portions of the elevations there is little of interest, for the admiration it has received has been due to its associations, and to the charms of certain details, rather than to any excellence of the composition as a whole. The heavy box-like upper story comes down with apparently crushing weight, upon the pierced arcades below, and if it had not been for the relief given by the application of colour to the vast plain surface, the effect would be much worse than it is. The whole wall space, where not perforated by windows, is covered with a diaper pattern, composed of pieces of different coloured marbles. The effect is curious, rather than satisfactory; but if the object were to lighten the appearance of a great unbroken mass, the expedient must be pronounced successful, to a considerable extent. The general question of coloured decoration is a point on which it is difficult to insure any consensus of opinion, for it is largely a matter of taste. The addition of the work of the sculptor and the painter to a structure will not make the latter architecture, if it be only building; and still less can such a miracle be effected by the humbler efforts of the decorator or the veneerer. To test the architectural merits of an edifice, we may ask, how would it appear if destitute of the added ornament of colour? If the upper story of the Ducal Palace were painted in a uniform grey tint, could it be admired as a work of art? Or take another instance; would not the Church of St. Mark, Venice, lose all its charm if the varied hues, rich mosaics, and costly marbles were obliterated? Colour may add to architecture, but it cannot take its place; and though it may modify objections, and soften deformities, it can never atone for bad art. Poverty of design will always declare itself, and it is never more objectionable than when it puts on the disguise of ill-considered contrasts of particular coloured brickwork. It is the architect's business to build pictures, not to paint them. The Italian architects were not accustomed to vary the colour of their brickwork, which was generally red. Where variation was desired, it was obtained by a sparing use of stone or marble. With us, to whom it is easy to obtain bricks of different colours, the temptation to use a variegated surface has proved irresistible, and has injured many a good design, cutting it up into small parts, so as to resemble a pavement set on end, or Tunbridge-ware manufactures. Decoration of this kind should be temperately applied, if it is to please, and the lines of colour should have reference to the constructional forms of the building in which it is used. The horizontal courses of black and white marble, to be seen in Italy, in the Broletto at Como, and the cathedral of Siena, are open to question, and would be more pleasing if the contrast of colour were less marked. The great opponent, however, of colour in English architecture is the damp atmosphere, and the smoke and dirt of our great towns. Public buildings with us begin to lose their beauty almost before the scaffoldings are removed, and the most delicate details, whether of carving or of colour, are the first to disappear, in dismal smears of blackness. Until some improvement can be obtained in this matter, the architect's work is somewhat disheartening, and delicacies of expression in external work are put out of his reach. In this scientific age, asked Professor Barry, is chemical discovery, which in its pursuit of gain has poisoned rivers, and rendered smiling valleys as bare and desolate as if a plague of locusts had ravaged them, powerless to aid in purifying the air we breathe?

On Wednesday, the 12th of February, the Church of St. John, Great Yarmouth, was reopened after the addition of north aisle, transept, and porch. The cost of addition is about £1,050, including benching, and 180 fresh seats are provided. The works were carried out under the superintendence of Mr. H. Olley, the architect.

GAS IN THE HOUSE.*

A HANDY little brochure under this title offers some very sensible remarks upon gas lighting. Its author, Mr. H. Faraday, wisely refrains from taking a partisan's view of the merit of gas as a lighting agent, for he frankly admits the superiority of the electric light, but he shows truly enough, as gas was tardily adopted and struggled into use long after the discovery, so it is certain that the electric light will take a long time before it takes the place of gas for domestic use. At least it is certain not to die a sudden death; for, notwithstanding the supremacy of gas, there is still, as we are told, a brisk demand for oils and candles. Mr. Faraday proceeds to lay down a few rules, and to offer some suggestions that will be read with interest just now by the gas consumer. The trade of gas-fitting has no doubt fallen into disrepute from the indifference of customers when ordering fixtures, though we are inclined to think also the gas companies have not been so liberal nor so eager to promote efficiency as they might have been. Among the practical rules given by the writer are the following:—That no pipes of a softer material than iron or brass should be hid from sight; all pipes in basement should be laid with a slight fall towards the meter, thus lessening the chances of obstruction from condensed gas and assisting the upward pressure; no gas pipe under 5 feet should be of less bore than $\frac{1}{2}$ in.; if for more than 2 burners not less than $\frac{3}{4}$ in.; over 6 burners $\frac{1}{2}$ in.; 10 burners $\frac{3}{4}$ in.; 15 burners 1 in., and so on, while in pipes outside building, these sizes should be doubled nearly, to make allowance for internal corrosion. No metal burner or outlet should be used, for the metal is apt to corrode and impair shape of flame. Burners of varying cheek power should be distributed throughout the building, with due regard to the average gas pressure at each light, so as to avoid fizzing and drowning. All gas used for heating purposes should be consumed in a burner that provides an intermixture of air before ignition, and the flame should burn blue. Gas stoves should have a discharge tube for the burnt gas, of not less than $2\frac{1}{2}$ in. diameter, which tube should communicate with a brick flue. All pendant fittings not of iron, or not strengthened by an interior tube of that metal, should be provided with a cup and ball, or other loose joint at top. No globes should be used with fish-tail burners that have an opening at bottom of less than $2\frac{1}{2}$ in. diameter. For small gas escapes ordinary yellow soap slightly moistened, is a good temporary remedy. Referring to ordinary lighting fittings, it is recommended that for basements the tubes be of iron instead of brass. For halls, a lamp with large door and divided panes that may be readily cleaned is preferred, the vestibule globe lights being expensive, and when broken not easily repaired. The author justly thinks it inhospitable to leave the steps to entrance in darkness, and for this reason pleads for the fan-light lantern which lights both interior and entrance steps at once. He thinks, however, these lamps may be made more interesting and architecturally in harmony with the lines of doorway, and also may be adjusted so as to make the number on door discernible at night time. For the dining-room the fidgety jets of gas from a chandelier are condemned, and the argand or ring-flamed burner recommended in its place as more powerful and steady. It may be fitted up with a large opal reflecting glass and fringe. The same burner is suggested for the library, and a ventilating pendant. For staircases, a bold scroll arm from landing supporting a central hanging lamp, is preferred to wall brackets, or perhaps standard lamps fixed to the newels of stairs. The hints on fittings are useful, and we are glad to find polished brass recommended. Sunlights are spoken of as the best means of lighting large halls, staircases, picture galleries, and smoking-rooms; and gas-pipes and stoves are advocated for bedrooms, as they create no dust or smoke, and require no raking or stirring.

The death is announced in Munich of the well-known historical and fresco painter Michael Echter. He was a pupil and admirer of Kaubach, whom he took for his model, though the latter was only a few years older than himself, and whom he aided in the execution of his famous staircase pictures in the new Museum at Berlin. He was born in 1812, and his career was brought some time ago to an early end by the loss of sight.

MAYO COLLEGE, AJMER, INDIA—CONDEMNED CHURCHES IN THE CITY—LLANERCH PANNA, NEAR ELLESMERE—WALL-PAPER DECORATIONS, BY JEFFREY AND CO.

OUR LITHOGRAPHIC ILLUSTRATIONS.

MAYO COLLEGE, AJMER, INDIA.

THIS exceedingly interesting design, by Major C. Mant, R.E., the architect for the proposed Mayo College, about to be erected at Ajmer, India, is well worthy of illustration as an adaptation of the native styles of architecture to modern requirements. Usually a sort of Classic style of architecture has been employed for the modern buildings in India, such as the Court of Small Causes, Calcutta, erected by Mr. Hugh Leonard, Chief Engineer to the Government of Bengal, assisted by Mr. W. H. White, F.R.I.B.A., while on the other hand several very clever buildings have been erected after the Gothic manner, chiefly in the style of Early French, by Mr. Wm. Emerson,* long time resident in India. We have also buildings in the Gothic style, by Sir Gilbert Scott, Mr. Roger Smith, and others. Major Mant however, has boldly taken the indigenous ancient style, and we venture to think has produced both a suitable and essentially modern building. The several apartments are clearly shown by the ground plan given with the view.

CONDEMNED CHURCHES IN THE CITY.

SS. Anne and Agnes.—Formerly called St. Anne-in-the-Willows, but for what reason is not known. This church has been twice destroyed by fire—in 1548 and 1666. After the last fire the parish of St. John Zachary was united to SS. Anne and Agnes, and the present building was finished by Wren in 1680 at a cost of £2,448 0s. 10d. It was afterwards "beautified" in 1703.

St. George, Botolph-lane.—The first authentic date of this church is 1321. It was rebuilt after the Fire by Wren at a cost of £4,509 4s. 10d. At the west end is a tower of simple proportions 84ft. high, but which cannot be seen to any advantage owing to the extreme narrowness of the surrounding lanes. The sketch herewith shows the east front. These drawings, together with those given Dec. 6th, 1878, were made from sketches on the spot by Mr. Robert Kendrick, of Warrington, and Mr. Jesse F. Scott, Stamford Hill, London.

LLANERCH PANNA, NEAR ELLESMERE.

THE two views and plans of this house illustrate clearly its arrangement and construction. The principal block is now nearly completed, and the kitchen offices will be erected when the old house adjoining is removed. It was desired to construct the building in the timber framework which was once so generally employed in Shropshire and the adjoining counties, and the whole of it has been executed solidly in English oak, and filled in with brickwork, which is covered with cement between the timbers. The chimneys are faced with red Ruabon bricks, and the roofs covered with brown tiles. The windows are filled with lead lights, those in hall having

shields bearing the arms of the Kenyon family. The hall, dining-room, and Mr. Kenyon's room are lined with old brown oak panelling up to the ceilings, the chimney-pieces, doors, &c., being designed to accord with old work and executed in oak. A gallery is carried round the hall at the level of the chamber floor, communicating with the various rooms, and leaving the centre portion of the hall open to the roof, which is open timbered. Mr. W. E. Samuel, of Wrexham, is the contractor for the work, which is well carried out. The architect is Mr. John Douglas, of Chester.

GOLD MEDAL WALL-PAPER DECORATIONS.

OUR double-page plate this week is devoted to the illustration of the two designs for wall-paper decorations to which the gold medal of the late Paris Exhibition was awarded last year. The authors of the designs are Messrs. B. J. Talbert and Walter Crane, and the manufacturers are Messrs. Jeffrey and Co., of 64, Essex-road, Islington. We have seen the several renderings of these patterns, and they are certainly equal to anything of the kind which we have seen before. The richness of colour and spirited drawing in Mr. Talbert's design is well worthy of its author. The frieze, which in this design is but 11½ inches deep, carries out the treatment of the sunflower as employed for the general wall paper. The dado is of a geometrical pattern, well suited to its position, and capped by a rich band of continuous ornament. Mr. Crane's design is very delicate, and quite characteristic of this well-known artist. The author thus describes his design:—"In the arabesque, the ever-ascending stem and interlacing branches may figure the constant growth of an ideal life, like a tree bearing flowers and living fruit. Amorini suspend its festal garlands, and light the flame of its thoughts, or play with the masks of grief and gladness, overhung by the bow and quiver of Love, and crowned with his roses. Pride and splendour as of the peacock lodge in its boughs, and the craft of the serpent is ruled over by the benign wings of the dove, while the corn is ever in the sickle, and the cornucopia full of fruit. In the frieze, the peacock stands as the emblem of the day. As in the arabesque and the frieze we have the elements of the earth, air, and fire of life, so may the dado be emblematic of the 'water which is under the earth,' or the cold and silent hours of life which glide by like the silver fish in their spheres." We hope shortly to devote another page to the illustration of two similar designs for decoration, manufactured by Messrs. Jeffrey and Co.

COMPETITIONS.

NEWTON ABBOT.—Ten designs have been submitted for the proposed Coffee Tavern at Newton Abbot. The first premium of £20 has been awarded to Mr. Charles Jenkin Jones, of 8, Buckingham-street, Adelphi, architect to the London Coffee Tavern Company, and the second premium of £5 to Messrs. J. W. Rowell and Son, architects, of Newton Abbot and Torquay.

SOUTHPORT PROMENADE EXTENSION SCHEME.—Sixty-seven sets of designs were sent in to the Improvement Committee of the Southport Corporation in competition for the awards of thirty guineas, twenty guineas, and ten guineas for the three best designs for carrying out the scheme of extending the Promenade as far as Park-road at a cost of £40,000 or £50,000. After examination this number was reduced to fifteen, and the fifteen to three—"Vive la Mer" "Sexagesimus," and "Advance," to which they recommended that the prizes should be given. On Monday night the General Purposes Committee met and confirmed the recommendation. The successful design—"Vive la Mer"—is the production of Mr. G. Heaton, architect, of Wigan. "Sexagesimus" is the design of Messrs. Goodison, Atkinson, and Ford, of Liverpool; and "Advance" that of Mr. J. Sidebottom, of Blackpool. It is expected that the extension scheme will now be pushed forward with all speed.

WEDNESBURY.—In the recent competition for the two schools for the Wednesbury School Board, as we stated on p. 143, the designs of Messrs. Alexander and Henman were successful for the schools in Lower High-street, and those of Mr. Ettwell, of West Bromwich, for the New Town Schools. For the former the plans of Mr. R. F. Matthews, of Birmingham, and for the latter, those of Mr. C. Newman, of Wednesbury,

were placed second, the designs of Mr. S. W. Grant, of Duke-street, Adelphi, being third in both competitions.

SCHOOLS OF ART.

LINCOLN.—At a meeting held recently in the Memorial Hall, Lincoln, resolutions were passed appointing a committee to consider the desirability of purchasing the old Lincoln County Hospital for the purposes of an art museum. At the close of the meeting the annual distribution of prizes to the students at the School of Art took place. The report spoke of the excellent character of the work done during the year. One silver, and three bronze medals, three Queen's Prizes of books, and fourteen third-grade, and nine second-grade prizes, had been awarded by the Department, who had also purchased a study in chalk. At the second-grade examination in May, 43 were examined, of whom 41 passed and nine obtained prizes from South Kensington. A number of local prizes were also given. The silver medal offered by Alderman Rorston was awarded to Henry Elmitt, a pupil with Messrs. Bellamy and Hardy, architects, of Lincoln, the fourth medal carried off by pupils with this firm.

PARLIAMENTARY NOTES.

THE GAS COMPANIES.—Sir W. Lawson, on Monday, asked the Chancellor of the Exchequer whether the Government intended to bring in any general measure with reference to the gas companies in case the electric light should be perfected for general use. The Chancellor of the Exchequer said the Government had no general measure of that character. He understood from his hon. friend the Chairman of Ways and Means that he proposed to refer the various private Bills introduced this Session to one strong committee.

PREVENTION OF FLOODS.—In answer to Mr. A. Peel, Mr. Cross said that the Lord President would before long introduce in the other House a separate measure dealing with the question of River Conservancy and the Prevention of Floods.

THE NEW LAW COURTS.—Mr. O. Morgan, on Tuesday asked the First Commissioner of Works whether he could state when the new Law Courts would be sufficiently advanced to admit of the transaction of business. Mr. Noel.—There were originally two contracts for the new Courts of Justice; according to one the eastern wing ought to have been completed during the year 1877, but, unfortunately, owing to frosts, strikes, and other unforeseen circumstances, the work was delayed; but I am happy to state that it is now ready for occupation, with the exception of some minor details connected with furniture and fittings. The legal authorities are now considering the question of the apportionment of accommodation and of removal, which will take place at their convenience. The main building should, according to contract, be completed during 1880; but it is impossible at this moment to fix any precise date at which it will be finished, but every exertion shall be made to hurry on the work.

A Local Government Board inquiry was recently held at Caerwys, near Wrexham, by Major Tulloch, with reference to a proposal to supply Caerwys with water from Flynnon Deg, and for the formation of a special drainage district. It was stated that the scheme was prepared by Mr. Humphreys, the sanitary inspector, and was to pump water from Flynnon Deg at an estimated cost of £400. The area of the proposed drainage district was 25 acres, the population 370, and the rateable value £5,000. Major Tulloch said he had never heard of so small an area, and could hold out no hopes that it would be sanctioned by the Local Government Board. It was eventually agreed by the meeting that application should be made for the whole parish to be constituted into a drainage district.

A meeting of Freemasons was held at the Freemasons' Tavern, Great Queen-street, W.C., on Tuesday week, for the purpose of forming a committee to restore in whole or in part the west face of St. Alban's Cathedral. Mr. John Chapple, the clerk of works at the cathedral, explained the work proposed to be done, and the committee was appointed, Earl Skelmersdale being nominated as chairman. The maximum subscription was fixed at £5, and a preliminary list was read.

The Rural Sanitary Authority of Erpingham, Norfolk, having applied to the Local Government Board for sanction to borrow a sum of £5,000, an inquiry was held, before Major Hector Tulloch, at 11, on Wednesday week. After hearing evidence for and against, and viewing the town, the inspector said he should intimate to the Board that the proposed scheme of drainage was not wanted, and that the water scheme was impracticable.

THE "BUILDING NEWS" DESIGNING CLUB.

REVIEW OF DESIGNS FOR GROUP OF THREE COTTAGES.

THE objects of good planning in cottages are obviously comprised under one word—"economy." The entrances should be contrived rather as internal lobbies than as conspicuous features; the stairs may be well made to occupy a portion of the space so set apart; the living-room should be easily accessible, of a good size for a man, wife, and three or four children, and in convenient proximity to the kitchen. There should be no waste passage room, unlighted corners, or unnecessary wall space. These conditions in the present competition seem met by "Yesram." The ground area occupied is about 54ft. by 23ft. exclusive of offices, and is well disposed. The end cottages have side lobbies with stairs slightly projecting, which lead into a front living-room, in each case 13ft. by 11ft., and into a kitchen 10ft. by 9ft., in which there is a pantry obtained under the stairs. The wash-house, oven fuel, and w.c. are desirably placed as a back projection. Above are two bedrooms. The centre cottage divided by straight party walls—a rather advantageous provision, we consider, sanitarily regarded—is, of course, different in plan. A front lobby with stairs gives access to a parlour in front, a living-room behind, out of which opens a small kitchen with sink at the back; beyond, separated by a space for light to kitchen, being the wash-house, and conveniences. Above are three bedrooms. There appears to be no waste space, and the author has certainly produced a compact group of dwellings, the main block of which is calculated at 23,302ft. cube, at 6d., and with the offices is estimated at £688. The elevation has the great merit of being simple and appropriate, relief being obtained by the tile hanging of the upper story and the timbering of gables. Motto "J." has some good points in plan. The lobby stairs and pantry are well combined in the end cottages, in a similar manner to the first; but there was no necessity for a parlour and living-room to each cottage. The living-room is made to answer for a kitchen in the end cottages, beyond which is a scullery with pantry. In the centre-house the scullery and conveniences are combined in a projecting back wing. The upper floor is commodious, three bedrooms being obtained to each cottage. The author, as usual, sends a picturesque elevation in which timber and plaster are used in the upper story, but the drawings are very crowded on the sheet. Estimate is £900. The plan of "Omnia Vineit Labor" is clever in the entrances, though the overlapping of the bedroom of middle cottage upon the kitchen of the end house is not desirable. All three cottages are differently arranged. The porches and stairs are compactly combined, and the kitchen and scullery lead out of the living-room in each case, but the stairs in centre are ill lighted. In the elevation we have a pleasing combination of brick and tile effective in the main. The cubing is put at 24,380ft. at 6d., £609. "Star in Circle" exhibits some good planning, the entrances at ends are compact, the ladder being placed under the stairs ventilated and lighted. The living-room, 14ft. by 10ft. 6in. is made to answer as a kitchen, and out of it opens a washhouse. The plans all vary. The elevations are in a neat and appropriate style, though the grouping at ends is not agreeable. The cubing is put at 33,186ft., and, priced at 6d., equals £829. The end cottages of "S in circle" are generally well planned in the entrance lobbies and stairs; in one case the washhouse is made to enter directly out of living-room, which serves as a kitchen as well. We do not like the narrow passage entrance to the centre house. The coals, ashes, and closets are placed in a row at the back, under a lean-to roof; this is perhaps unobjectionable in the country, but the coals would be better stored under the roof. The bedroom plan shows 4, 3, and 2 bedrooms respectively—a good arrangement, and the division walls are straight with a slight exception. The landings are lighted, and the closets are useful. Externally there is considerable variety obtained, as the end entrances are dissimilar, and in one case the upper story is made to project over the porch. We do not admire, however, the disjointed effect of the right-hand side cottage, caused chiefly by the roofing. The cubing is worked out at 24,984ft., and is priced at 6d., £641 16s. "Enigma" is certainly economic in plan, and the end cottages are replicas. The pantry would have been better

leading out of kitchen or living-room than wash-house, and there is rather a roundabout approach to the fuel store. The upper story is tiled. Estimate is £540, the cubing being 21,600ft. only. "Such a Dog" is the motto of two alternative sets. One design shows the group combined as a right angle, two cottages on one side and one cottage on the other. The porch entrances are somewhat circuitous in arrangement, but the washhouses are conveniently placed. We do not like the suggested position for the water-closets: they are certainly better outside; ash or earth closets are preferable. The alternative plan shows a back-to-back arrangement of two cottages, compact, but the stairs are ill-lighted. The elevations are simple and appropriate. "Spero Meliora" rather exceeds the requirements of country cottages; the lobbies are too large, and the parlour in one case is beyond the demands of the working man. Generally the plans are well studied, and the elevations are suitable. Estimate is £950. "Crowquill" also transcends the average cottage, and externally the design would be more suited to a suburb of a town. The end cottages are similar in arrangement of plan, and the front angles form canted bay windows, though for what purpose the heavy stone corbelling above is introduced we cannot imagine. The washhouses form a detached block in the rear. We do not see a coal store. The drawing is creditably executed, and the estimate is £704. "M in Leaves," like the previous two, falls into the error of providing larger rooms than desirable. The passage entrances are quite unnecessary for the working classes; they entail labour in cleaning and need a watch over the front doors. The author provides back covered yards for washing purposes, and reduces his scullery to a "wash up sink" out of kitchen. These are the best parts of plan. "T. W. P." sends a clever, but rather straggling plan. The entrance and stairs are placed opposite each other in each cottage, though irregularly distributed, and the rooms are located on each side of entrance, rather objectionable, inasmuch as it places one room beyond the control of the housewife, if she happens to be engaged in the kitchen or washhouse. The latter is made to form a single building detached from the cottage, and to be used jointly; the coals and w.c.s. are placed round the same outside block, a by no means desirable arrangement. The design of "W. J. M." is well drawn, but much too ornate in style for cottages. Such ornamental bracketed door canopies and the cross timbering are surely out of place in dwellings for agricultural labourers. The plan is more in keeping, but the broken party walls and the arrangement of centre staircase are defects. "Ieh Dien" is a neatly drawn set; but the remark we have already made about a passage access to the rooms applies to this. A large class of the designs we have received give us more than we asked for, though a few are creditable as drawings. Among these we place the design under motto "Be to its merits very kind, &c.," the author of which seems to have somewhat mistaken the object of these competitions, in contributing a set of elaborately figured plans, sections, and a full specification. To do him justice, we may say they are highly creditable as technical drawings; but we may repeat here, chiefly to save him useless labour, that the only drawings we need are those which illustrate the general scheme and design. The plan sent has one or two obvious defects. The entrances to end cottages lead directly into the living-rooms, and the central passage is defective. Why cant the corner? and what object is there in the huge corbelling of angle above door? The details show knowledge. Other designs creditable as drawings, in which the object of cottage design is lost sight of, are "Un Jeune Elève," "Olive Branch," "J. C." in circle, "To be, or not to be." "Club in circle" makes one washhouse answer for the three cottages; the end cottages are well arranged, but the elevations are too costly. "Leo" sends a simple plan, but with separate outbuildings; "J. S." has some good points, the elevation has a fussy look but is not without merit; "W. in Triangle" is bewildering in plan, and the party walls are crooked; and the same remark may be applied to plan by "Corvus," whose arrangement lacks contrivance. "L. in G." is suitable in treatment, but the out-offices are crowded, while "Montague" spoils a tolerable plan by attempting variety in his elevation. "Reseda" appears to have something in it, but the break in the centre cottage is unmeaning. We have no space left here to criticise other attempts, many showing misdirected labour and

some skill in drawing. We may name in order of merit "Burswell," "Yes or No," "Maltese Cross," "Revus," "Try," "Ostreich," "Tam O'Shanter," "X. L." "Steffano," "Spider," "Y. Saer Bach," "Thor," "G. in Shield," and "Ognore."

We cannot avoid here giving a few words of advice to many of the latter class. Study the grammar of planning, and never attempt an elevation until the plan is thoroughly worked out and reduced of all superfluities. We recommend, for the first, a perusal of an article which appeared in the *Building News* a year or two ago, besides an examination of good plans; and for the second, a strenuous exertion to bridle the fancy.

DESIGN FOR STONE PULPIT.

We are well aware that a stone pulpit is a difficult subject for design, as many architects err in the attempt; and lest any of our contributors should be disposed to quarrel with the award, we will just state what we consider to be axiomatic principles of design, and upon which we have based our selection. In the first place, to attempt to design a stone pulpit like a wooden one would be manifestly wrong. The outline and details must be essentially suited to masonry; the base should be massive, the ornamentation confined to moulding and relief, and attenuated tracery strictly avoided. Upon these principles then, we consider motto "J" has arrived at a fair solution. The design is Classic in conception. The pulpit is built up from the floor rectangular in plan, while the side, front, and ramp of stair is simply jointed ashlar of Ketton stone, relieved by a moulded cornice with egg and tongue enrichment as a capping and book rest, and a carved sunken panel beneath. Inside, the pulpit is lined with oak panelling. Next in merit comes "Triangle in Circle." Here a little more freedom has been displayed, the square front of pulpit being broken by a circular corbelled projection, quite plain; the only relief being carved diaper ornament up the sides and round the base of projection. The style is Gothic, and the detail is effective, though the drawing is poor. The author of the third best design, "K in Circle," has, by mistake, sent a font for a pulpit—an error that, of course, excludes him, and we only mention his design as conforming to correct notions of design. "Bad Attempt" is certainly rough in drawing, but the design is not wanting in simplicity and character. The author supports a circular pulpit upon a massive central shaft, surrounding which are three smaller shafts with caps and bases. We do not like the sunken panel and cross, though the details are good. "Signum" is perhaps next in merit. The pulpit is constructed on a square base of ashlar, the front of which is made to project on angle shafts. "Nemo in Shield" is a plain circular pulpit standing on a massive stem; the ornamentation is appropriate, with the exception of the capping, the metal scroll work, and the newel of balustrade. "Burswell" adopts a square form, suitable but for the panelling. The elevation looks octagonal from improper shading. "Prenez garde" is much too florid, and the details are somewhat coarse, especially the base mouldings. Another class of designers have adopted the framework idea too much; "East Anglian" is one of the best of these; "Try" is another, but fails in his mouldings; "Namor" has the germ of success, but the base with its huge scotia and the mouldings destroy an otherwise reasonable design; "Dunwich" attempts too much; there is something good in the idea, but the details are extravagant. The corbelled base is spoilt by the puny and crooked angle shafts in a very unnatural position, and the inter-penetration of the angle pillars is absurd. "Amateur" is too bombastic, and there is a useless display of ornament. It would be throwing words away to criticise a design which makes the final of a centre arch a book rest. "Try" endeavours to be too ingenious; the plan is capricious. We can only name "Fleur de Lis," "Con Amore," "B. M. W.," "Be to its merits, &c." Many of these are far too elaborate and costly for a country church pulpit.

At Burton-on-Trent county-court, on the 5th inst., a case was heard in which J. A. Mason, architect, claimed £15 for plan of building prepared and supplied to a Mr. Christian. The defence set up was that the designs were too expensive, and were never used, and the judge (Mr. Woodford) gave judgment for plaintiff for £3.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

(Concluded from p. 185.)

THE author further urged, that not only were these matters of arrangements of approaches and general appearance thought out, but that the given points of sight and the apparent magnitudes were the subjects of consideration; and calculations were made in order that the designs should appear to the spectators as perfect in apparent proportions as they were first conceived in the architect's mind. The idea of a point of sight was not, he admitted, new; but that the Greeks should have corrected all the apparent vertical magnitudes, so that in the finished design they should all be commensurable one with another and with the apparent whole height, and then have trigonometrically calculated and corrected all the executed heights in the finished design to suit a favourable given point of view, required actual proof. The evidence was based, firstly, upon the written statements of Plato, Aristotle, and Vitruvius, who all clearly referred to a favourable point of view, to the apparent magnitudes, and to the corrections made in the original design by certain "additions and diminutions." Secondly, the measurements of the Athenian porticoes showed clearly that certain small plus and minus quantities had been either added to or taken from the original dimensions of the porticoes, as given in the canon of proportion. Thirdly, by simple trigonometrical calculations commencing with the given quantities, the true executed dimensions might be arrived at, which in every case would agree with the measurements. To establish the first point, a number of corroborative passages were quoted from the three authors named. But we need not trust to the correct interpretation of these passages, for if such "additions and diminutions" were really made upon the original designs when designing, we must expect—upon examination of all architectural works of magnitude executed, either in Greece or in Asia Minor, during the best period of Greek art,—to be able to discover by measurement the actual amount of the variations made in the heights of the several members of each design when subjected to those corrections essential to produce apparent harmony between all the parts of the finished executed design; and this was, he urged, really the case. Sufficient space was allowed for the eye to embrace the line of greatest extent (usually the diagonal line of the temple) within a given horizontal visual angle of 45° , and this horizontal angle of 45° was dealt with as a fixed quantity. Vitruvius refers to the special calculations required for determining the apparent magnitudes, and the additions and diminutions that have to be made, but before this could be done certain quantities must be given. Firstly, this is done for the Greek porticoes when the first given heights, widths, and projections are all laid down according to a fixed canon of proportion. Secondly, upon the horizontal plane—"the plan exhibiting the length and breadth of the whole work, and the several parts of it, must be formed," and the position of the point of sight must also be given upon this plane, "so as to comprise the whole extent of that scale which the eye is able to embrace at one view." Thirdly, the position of each design upon its artificial platform with regard to the point of sight and the height of the upper step either above or below the horizontal plane must be also given. The temple is now supposed to be fixed in position with regard to the point of sight—the given dimensions are all commensurable, and if there were no corrections to be made we might at once proceed with the designing of the columns and the entablatures. This is actually the case in some small designs, but not in the Greek works of magnitude. In these cases certain corrections have to be made by calculation, so that the perspective design may appear to the spectator to be perfect in apparent proportion, and the slight irregularities were thrown into the executed work, where they escaped detection. The horizontal straight lines have also to be converted into convex lines. Speaking generally, the calculations for determining the apparent magnitudes are found to assume a twofold character; firstly, position, and, secondly, the executed dimensions. This was fully explained by reference to diagrams representing the Parthenon, and it was shown that all positions were rendered commensurable with the given canon of proportions, and that the apparent dimensions were

made commensurable by substituting for the apparent irrational quantities the nearest angular magnitudes, and the slight irregularities were finally thrown by calculation into the executed height, so as to cause perfect harmony between all the apparent proportions. The second important correction that the Greeks made upon the masses of their architectural designs was the substitution of curved lines in their larger works of architecture, instead of the horizontal straight lines. The first accurate study of these curved horizontal lines was made by Mr. Penrose, who visited Athens in 1846, and measured and observed them with scientific skill. He measured the curvature of the lines in the sub-basement of the first temple of Minerva in the Acropolis (built about the 8th century, B.C.) as follows:—Length of the front 104.2ft., amount of curvature in vertical plane at centre 0.15ft.; length of flank 221.0ft., curvature in vertical plane at centre 0.233ft. This is probably the oldest existing example of the curvature of the horizontal lines of Greek architecture. But the principal development of these curved lines is in the designs of the age of Pericles, and of all the horizontal curves now remaining, the best preserved and the most carefully executed will be found to be in the upper step of the Parthenon. When speaking of the curve of the upper step at the east end, Mr. Penrose says, "A circle drawn so as to pass as near as possible to all the measured points, taking them in their actual positions, would be subject to an error of only .0065ft." The agreement is evidently so close between the measured and the calculated ordinates, for all four sides of the Parthenon, that we may safely identify them as the arcs of similar circles. The entablature of the Parthenon has as it stands certainly a curvature in a horizontal as well as in a vertical plane, but the former curvature appears to have resulted from the concussions which have so seriously shaken the building, and not from design. The columns are of exactly the same length, so that the curve of the entablature follows that of the upper step. The second part of Mr. Pennethorne's paper dealt with the working out of these general principles, in the column and entablature, and the minor details of the buildings. Here a new feature had to be introduced, the application of the conic sections to the outlining of the mouldings, ornaments, capitals, and all details of Greek art, and although there is no written work upon the conic sections earlier than Apollonius, B.C. 240, yet traces of these curves are found in all the marble remains of the Greek temples, and there was reason to believe also, in the outlines of some Egyptian cornices, and shafts of columns. In the designing of the Greek entablatures there are no corrections to be considered, but the whole entablature from the first is perspective proportioned, and arranged to suit the given point of sight; and this is the case in the designing of all the entablatures, whether in Athens or Rome. Dividing the whole apparent height into some given number of aliquot parts, the apparent height of the architrave, of the frieze, and of the cornice will in each case be a multiple of this given modulus. Again by dividing the first modulus into a given number of apparent aliquot parts a second modulus is obtained by which the apparent heights of all details of cornice, of architrave, and of frieze will be regulated, and the true lineal heights are then all determined by trigonometrical calculations. In Greece the curved outlines of the ornaments are generally traced upon curved surfaces, which become the mouldings of Greek architecture. From direct observation we find that the curved profiles of the mouldings can be reduced into the arcs of a few simple mathematical curves, and can then be classed according to the number of curves combining to form the profile. The sections through the fascie are frequently curved surfaces, the section being either elliptical or hyperbolic, and the sections through the soffits of the cornices are also the arcs of conic sections, either of the hyperbola, of the parabola, or of the ellipse. The designing of the ornaments is complex, owing to the multiplication of the curves one within another, but when a single outline is taken, the curve is found to be simply the arc of one or other of the conic sections, easily traced by descriptive geometry from the given elements of the several curves. The first ideas of the Egyptian columns were, Mr. Pennethorne believed, derived from the artistically-arranged offerings painted in the tombs, and on the temple walls. The Grecian Doric columns and entablatures were suggested

by those earlier Egyptian designs; but the Egyptian architects were guided in the design of the columns by the laws of proportion, and a knowledge of geometry. Between the designs of the Egyptian and the Greek columns are many points of very close resemblance, sufficient to prove that the first ideas of the Doric columns and the first principles of Greek art were both derived from Egypt. But in Greece we lose all trace of nature in the designs, and the columns, as well as the ornaments, are purely intellectual works of geometry, dependent for their beauty upon accurate proportions, upon true mathematical curves, upon a careful study of light and shadow, as well as colour, and, lastly, upon great precision in the execution of every detail. Athenian architects appear to have adopted a certain canon of proportion, both for the Doric and for the Ionic columns, thus—In the Doric

order the width of the abacus = $\frac{\text{height of column.}}{5}$
This is the case in the Parthenon, in the Temple of Theseus, in the Propylaea, north wing, and in the temple of Apollo at Phigalia. In the Ionic

order the width of the abacus = $\frac{\text{height of column.}}{8}$
This is the case in the three examples of the Erechtheum, and in the Ionic temple of the Ilissus and at Priene. The first masses of the columns being arranged, then the width of the abacus is always divided into some given number of aliquot parts, as 14, 15, 16, &c., and one of these parts being taken as a modulus, then the upper and lower diameters of the columns, and in the Ionic order the height and width of the capital and of the base are made multiples of this modulus. All the details of the columns, as well as of the entablatures and ornaments, were invariably proportioned in aliquot parts. The Greek architects made a finished coloured drawing of the whole design, taken from some angular point of view, and showing the sculpture, painting, and architecture all combined; this was known as the *Scenograph*. It would, however, require the artist feeling of a Raphael or of a Claude to reproduce copies of these original drawings of the Greek artists, but the materials exist in the remains of the sculpture, of the painting, and of the architecture, and in the position of the Acropolis itself in the plane of Athens.

LEGAL INTELLIGENCE.

CONSEQUENTIAL DAMAGE.—Mr. Under-Sheriff Birchell, on Monday, presided over a special jury at the Middlesex Sheriffs' Court in the case of "Fitzwilliam and Hall v. the London School Board," in which a peculiar question arose as to "consequential damage" to the Hall-park Estate, Paddington, by the London School Board taking two houses in Campbell-street for a school. Mr. Grantham, Q.C., and Mr. Anderson were for the claimants; Mr. Marriott, Q.C., and Mr. Freeman for the School Board. The sum of £462 7s. was agreed upon as to the houses, and the principal question was the damage to the rest of the estate by the severance. The evidence on the point was most conflicting. The surveyors for the claimants estimated the damage at £1,000, and described all schools as a nuisance to property, except of the lowest description. On the part of the School Board, several surveyors stated that so far from damage being done to the property by the school a benefit would be conferred on it. The neighbourhood was inhabited by artisans, and schools in such places did not injure property. One of the witnesses, however, admitted that to take two houses from an estate and thereby introduce a "foreign owner" was an injury. The jury, after a brief consultation, gave £424 for the severance, which, with the value of the houses, made the verdict of £886 7s.

WATER SUPPLY AND SANITARY MATTERS.

LILEBY, LEICESTERSHIRE.—The usual local inquiry for sanction to borrow £3,500 for drainage works for this township has been recently held before Major Tulloch, R.E., upon plans prepared by Messrs. Hodson, Price, and Hodson, of Loughborough. It is intended to provide sewers for all the streets, and the whole sewage of the three water-sheds of the township is brought to one point of outfall, where it is to be dealt with by irrigation over 3 acres of land. The only unusual feature of the scheme is that the proposed outfall ground is practically level, the greatest difference in level being only 0.4 of a foot.

Building Intelligence.

ARMY AND NAVY CLUB.—The Army and Navy Club, which has been closed since the 12th August last for extensive alteration and entire redecoration, from the designs and under direction of Mr. Hugh Roumieu Gough, of 6, Queen Anne's-gate, S.W., was reopened on the 17th of February. The principal alterations consist in the enlargement of lower smoking-room, by the addition of a corridor and of the former visitors' dining-room, making the area of new room 2,620ft., probably larger than the smoking room of any other club in London. The ceiling of the new portions of the room, as well as that of the visitors' new dining-room and new billiard-room, are very richly treated, and have been carried out in carton-pierre. One of the principal features of this building is its noble hall and grand staircase, occupying an area of 1250ft.; in this portion only has gilding been used, the iron balustrades being etched with gold on a "café au lait" ground. The general repairs and renewal of furniture were entrusted to Messrs. Holland and Son. The total cost of the works has been about £12,000. The bills of quantities for the builders' and decorators' work were supplied by Mr. Wm. Allport. Mr. Crawford Eyre acted as clerk of works.

BRISTOL.—The formal opening of the new Grammar School, Tyndall's Park, will take place after Easter. The style is that of the fourteenth century. The dimensions of the ground line are 158 feet by 68 feet, and the height to the terminals of the gables is 90 feet. The building is of red local stone, with freestone dressings. The ground-floor of the main building is divided by corridors, opening upon which are the cloak-rooms, the head master's rooms, and eight classrooms, each averaging 20 feet square. From the entrance a corridor leads to the western transept, where the principal staircase of Pennant steps and freestone balustrade leads to the upper floor, the whole of which is devoted to the large schoolroom, 140 feet long, 50 feet broad clear of the walls, and 50 feet high from the floor to the collar beam of the roof. The seats and desks provide accommodation for between 400 and 500 boys. The pointed roof is covered with green slate, and surmounted with terra cotta cresting. The clock has been supplied by Messrs. Gillett and Bland, of Croydon. The total cost of the building, including the site, will be nearly £20,000. The clerk of the works is Mr. George Salmon; the general contractors, Messrs. Williams and Sons. The gaseliers and pendants were supplied by Hardman & Co. The designs were furnished by Messrs. Foster and Wood.

CRICKSEA.—The parish church of Cricksea, in the Dengie Hundred, South Essex, was reopened on Sunday week, after having been entirely rebuilt upon the same site. The new church consists of nave, 36ft. by 19ft., with south porch and a chancel 20ft. by 16ft., with north vestry. As much of the old materials has been used as possible. The nave roof is open-timbered and tiled; and the west end is surmounted by a bell turret constructed of oak, and hung with oak shingle. The south doorway was the only architectural feature of the old church which could be re-used; it is of the Early Decorated period, and has been adopted as a key for the style of the restored church; the old stone doorway has been protected by a massive porch in oak. The chancel roof is close boarded with moulded ribs, and carved stones at the intersections. The furniture consists of Caen stone pulpit, stone credence-table, desk, lectern, and benches of carved wood. In front of the altar is an inscription in encaustic tiles, "Do this in remembrance of Me." The works in the nave have been carried out by Mr. Charles Read, of Burnham, Essex; and those in the chancel and vestry by Mr. J. M. Hayes, of Maldon. Mr. F. Chancellor, of London and Chelmsford, was the architect. The total outlay has been about £1,350.

DUBLIN.—New and extensive buildings are being erected at the terminus of the Great Northern of Ireland Railway Company in Amiens-street, Dublin, and are nearly completed. They are built of Belfast red brick and Dunfries stone. In the basement are the stationery department and the strong rooms. The board-room opens on the departure platform, and has an open roof and sunlights. Adjoining

are a new station-master's office, three waiting-rooms, lavatories, and lamp-rooms. On the second floor are a committee-room and secretary's, accountant's, engineer's, and traffic manager's rooms. The buildings have been erected under contract by Messrs. Fitzpatrick, Belfast, from the designs of Mr. Lanyon, of the same city, architect; the outlay has been about £16,000. The mantel-pieces, heating apparatus, plumbing, and gas-fitting were executed by Messrs. Hodges, of Dublin.

GUISBOROUGH SCHOOL BOARD.—In a résumé of their work during the last three years, the retiring Board state that they have carried out the Elementary Education Act to the best of their ability, with the restricted means at their command, and that towards providing proper school accommodation, they have effected the transfer from the Charity Commissioners to themselves of the Providence Schools, which represent property and securities to the value of upwards of £5,000. Of this sum £3,000 has been devoted to the erection of the new Providence Schools. The new Providence Schools provide accommodation for 789 children, with suitable teachers' residences adjoining, and are now almost completed and ready for occupation; and the Board state that they feel it due to their architect, Mr. J. Mitchell Bottomley, of 1, Zetland-road, Middlesbro'-on-Tees, to say that they believe that both for beauty of design and for practical convenience and comfort, these schools can compare favourably with any with which they are acquainted. The cost, inclusive of site, is £7,562, and the contractors for the whole of the work are Messrs. Sturdy Bros., of Middlesbro'. The Board state that their architect has prepared plans for the Northgate Schools, also providing accommodation for 789 children, but, owing to the depression in trade and other causes, they have proceeded with only the boys' and infants' departments, leaving the girls' school and the teachers' dwellings to be completed when a revival of trade and experience of the practical working of the existing schools may demonstrate the necessity for this. The contract for the Northgate Schools has been let to Mr. Richard Cass, of Guisbrough, for £3,285, and the site has been given by Admiral Chaloner.

HULL.—The first block of school buildings erected by the Cottingham School Board were formally opened on the 5th inst. They are intended to accommodate 300 children. The buildings are erected of brick with stone dressings, a conspicuous feature being a tower and spire containing the bell over the infants' entrance. The roofs are open-timbered, of pitch-pine, stained and varnished; and the lavatories, which have the walls lined with white glazed bricks, are fitted with Macfarlane's washing apparatus. The total cost of the buildings—which are of a substantial character—including the pavement, gas and other fittings, payment to clerk of works and every expense, will amount to £8 13s. 4d. per head. Mr. Robt. Clamp, of Hull, is the architect, and the works have been satisfactorily carried out by Mr. Mark Helas, the builder.

LIVERPOOL.—The Liverpool Reform Club was opened on the 6th inst. Granite, about 6ft. high, forms the base of the building, above which rises the main walling of Ruabon bricks, relieved here and there by Woolton red stone in the dressings. From the entrance hall the first or principal floor is approached by the grand staircase. On the right there is the reading-room, about 40ft. long and 27ft. wide. The remaining portion of this floor is principally occupied by the large dining or coffee-room, about 87ft. long and 27ft. wide. Continuing up the grand staircase, the smaller dining-rooms, smoke-room and billiard-room are reached, all on the second floor. The general contractors were Messrs. Jones and Sons, Liverpool. Messrs. Gillow and Co., Liverpool, supplied the furniture, and Messrs. Hardman and Co., Birmingham, the gas fittings and ornamental ironwork. Mr. Thos. Dove was the clerk of works. The building has been erected and the furniture supplied under the superintendence of the architect, Mr. Edmund Kirby, of Liverpool.

MANCHESTER.—St. John's Church, Deansgate, Manchester, was reopened on Feb. 13th, after restoration. An inner chancel, or "chorus cantorum," has been formed within the existing walls. The altar is of oak, open framed, and has been manufactured by Messrs. Cox and Sons, of London. Above the oak panelling

the walls of the sanctuary are decorated in colour and gold, with a banded diaper and four vesica-shaped panels. The plaster-groined ceiling of the apse is also decorated in colour and gold, and is powdered with stars. The work has been executed from the designs of the architects (Messrs. Medland and Henry Taylor) by the contractor, Mr. T. Scott.

METROPOLITAN BOARD OF WORKS.—At this board regulations prepared under the 12th section of the Metropolitan Management and Building Acts Amendment Act, 1878, with respect to the protection from fire of new theatres and certain new music halls, have been submitted to the Building Act committee; they were referred back to the committee with authority to send the same to the Lord Chamberlain and the justices of the peace for the City of London and the counties of Middlesex, Kent, and Surrey, with the view of obtaining their opinion thereon before they are finally settled and approved by the board. A letter was received from the Baroness Burdett Coutts, offering facilities for the removal of the Whitechapel hay and straw market from its present position in the High-street to her Columbia-market in the Hackney-road.

STAVERTON.—The chancel of the parish church of Staverton, near Totnes, has been restored, under the superintendence and from the designs of Mr. Ewan Christian. The roof, quite new, is of the local waggon shape, and of pitch-pine. Its timbers are decorated by colour, the ribs and purlins painted, and the carved bosses at the intersections gilded. Over the chancel proper the panelled boarding is varnished only, but within the sanctuary the ground is of blue, spangled with golden stars. The roof springs from wall-plates, in which are carved paterae, and at the western end spring corbels of stone, upon which are sculptured representations of angels in attitudes of adoration. The floors are laid with Minton's encaustic tiles; and by four steps of Robin Hood stone the ascent is made to the altar. The walls of the chancel are plastered and stuccoed a quiet colour. The reredos is in the main of moulded and carved stone, having a central compartment of wood highly decorated. The stone and wood carving and sculpture have been executed by Mr. Harry Hems, of Exeter; and Mr. Cudleigh, of Newton Abbot, is the contractor for the restoration generally.

TWEEKSBURY ABBEY.—At the last meeting of the restoration committee a plan prepared by the architect, Mr. J. Oldrid Scott, was exhibited, showing the proposed position of the large organ in the centre of the tower arch to the north transept, was produced and approved, and Mr. Willis's specification and estimate (£700) were accepted for the rebuilding of the organ, which was originally purchased for Magdalen College, Oxford, in 1637, and removed to Tewkesbury Abbey exactly a century later. A vote of thanks was proposed to Mrs. H. B. Moore, who has undertaken the restoration of the font and to provide for it a canopy. Plans of the choir stalls were also produced, and it was decided to proceed with those for the north side, leaving those on the south until further funds are obtained.

WARNEFORD DIOCESAN CHARITIES.—The following grants towards the erection, enlargement, and restoration of churches in the ancient diocese of Gloucester, were voted by the Warneford Ecclesiastical Trustees at their last meeting:—Bledington (additional) £100; St. James's, Gloucester, £250; Iron Acton, £100; Moreton Valance, £100; Northleach (additional) £150; Sutton-under-Brails (additional), £50; Tewkesbury (additional), £100; and Upleadon, £25; and towards the erection, repair, and alteration of parsonage houses:—Beachley, £50; Coaley, £100; Little Compton, £10; Minsterworth, £75; and Stone, £25.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Twopence, of all booksellers and news-vendors. Post free 24d. Office: 31, Tavistock-street, Covent-garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
(Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.)

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements is, per line. No front page or paragraph advertisement inserted for less than 1s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 3fr. 30c.). To India (via Southampton), £1 6s. 6d. (or 40s. 6d.). To the Australian Colonies, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

G. W. Ry. Co.—W. H. S. and Son.—J. F. B.—H. F. H.—B. W. M.—S. C. E.—R. D. and Co.—F. H. K.—D. and Co.—A. B.—L. and N.—M. H. and Co.—J. and Co.—T. L. and Co.—W. K.—T. H. C.—T. and Son.—F. and Co.

A COUNTRY STUDENT. (There is no such work as you require upon architectural drawing and shading, published in England, and the only work on shading of a practical kind we can recommend is Gwilt's "Sciography; or Examples of Shadows, and rules for their projection," published in 1834. If you want to learn the names of details of buildings, you must consult Parker's Glossary, Gwilt's Encyclopedia, or other work of an elementary kind, for which you appear to have such a contempt.)—H. J. PEARSON. (We cannot recommend you any work on prize drawings for cottages. "Cottage Construction and Design," by C. W. Strickland, published in 1864, and another work, "Hints on Cottage Architecture," by H. Weaver, may be of service.)

M. REED. (We cannot say. We have never had any other complaints, but we cannot guarantee the integrity of advertisers.)—E. A. P. (The plates are not sold separately.)—EXETER. (Many methods have been advised in back numbers. We believe the damp proof composition sold by the Silicate Paint Co. is an effectual remedy.)—J. KAYE AND CO. (We do not insert copies of letters sent to other journals.)

"BUILDING NEWS" DESIGNING CLUB.

B. M. W.—(We cannot account for the omission, and we now supply the criticism of the buffet. The general idea is not without merit; but the top ramps and side shelves spoil the outline, and the carved brackets on each side of mirrors are quite out of keeping with the end supports to the cove. We should have liked the design better if the ramps had been omitted.)

Correspondence.

THE ORIGIN OF THE SCOTTISH BROCHS.

To the Editor of the BUILDING NEWS.

SIR,—When I read in Mr. Fergusson's paper on the Brochs, the following catching sentence, viz., that "the great tendency of controversies of this kind is to get smothered in detail, and to such an extent as to obscure the main facts at issue," I knew some unwary critic would swallow the tempting bait, nor on perusing your article on the subject was I mistaken. The fact is that it is details and details alone that must decide the matter, for it is the character of the objects found in excavations in the brochs that must determine their origin and use, all else being simply speculation. Now, the objects found belong almost exclusively to the late Celtic and not to the Viking period, as anyone who chooses to examine the collections in the Museum of the Soc. Ant. Scot. may see for himself. This is the unpleasant objection to the Norwegian theory, which Mr. Fergusson makes no attempt to answer, and for an obvious reason—that it is unanswerable. Mr. Anderson is a practical working archaeologist who has examined and excavated a very large number of these structures himself, and is also curator of the Museum of National Antiquities of Scotland, and his opinion is consequently entitled to much more weight than that

of Mr. Fergusson, who as far as the brochs are concerned, is merely an amateur.—I am, &c.,
J. ROMILLY ALLEN, F.S.A. Scot.
23, East Maitland-street, Edinburgh.

CLERICAL DRESS IN 1750.

SIR,—As a sequel to my last letter, I may add that, having personally seen the interesting figure which Mr. Harry Hems had discovered, we are now agreed that it represents the Poor Man of Pinhoe standing appropriately on the top of an alms-box in the church, as I suggested. The date is, I think, the beginning of the last century.—I am, &c.,
MACKENZIE E. C. WALCOTT.

SEMI-DETACHED VILLAS.

SIR,—I was glad to see further attention called to the problems connected with semi-detached villas in your last number, a question which is of so much importance to a large section of the dwellers in towns and suburbs.

Having had some little experience in carrying out buildings of this class, I may, perhaps, be allowed to add a few remarks to those of Mr. Stedman. The good points in the plans of "S. in Circle" (illustrated in Jan. 31), are the provision of a lavatory out of the hall (a w.e. on the ground-floor is, I think, quite unnecessary in this class of house), the shutting off of the kitchen and offices and the garden entrance, though this latter feature cannot be considered needful, the dining-room window being a French encaissement.

The faults, I take it, are—the excessive projection of the kitchen and offices, which seem to make a strenuous endeavour to reach the bottom of the garden—and what appears to be the intentional blocking up of the through entrance to garden by the coals. The stairs are very cramped indeed. The kitchen window commands a great part of the dining-room. I hold with Mr. Stedman that the kitchen and scullery windows should be on the side where there must always be a high fence for the depth of the house, and on no account should either of these windows overlook the garden. There is some amount of waste space in the roof. The lowest price which can be generally reckoned near London for this class of property is 7d. per foot cube.

By the way, is not £800 cost rather too much for a semi-detached villa with only two reception-rooms?

If the kitchen is put by the side of the dining-room and the hall and stairs in front of it, with the entrance door in the front wall (leaving only the scullery and offices to be built out in one story), the house becomes square, and may be covered with a simple one-span roof. On first-floor there would be three bedrooms and bathroom, and separate w.e. over hall, with three attics and eistern or box-room in the roof. The depth of house being 33ft. and the width 26ft.

I have found the foregoing to work both economically and conveniently, costing about £1,400 a pair. I may add that by making the house 2 or 3ft. deeper and getting the main entrance on the side, a small library may be got next the drawing-room in front.—I am, &c.,
Feb. 10.

M. C. H.

ARTISTIC BLOWERS TO OPEN FIRE-PLACES.

SIR,—I see in the interior view of the Dining-room, Finchley-road, published in the BUILDING NEWS of to-day, a sort of dog grate is used with an open fireplace, and that the very necessary feature of an ornamental blower is introduced. Now that so many of us live in Queen Anne houses—or at any rate in houses where these admirable grates generally known as slow combustion stoves are used, having large openings over—the necessity of a blower is very much felt, and its treatment architecturally is worthy of consideration. I must say I have not yet seen it well treated in any modern Queen Anne building, while in a great many the tiles round the grates bear witness to the smoke which the inmates enjoy at times. For instance, when I went over the new School Board Offices on the Thames Embankment soon after they were opened, the tiles to the grates in nearly all the rooms were well blackened, and brown paper blowers were used. I wonder how they work now! This is probably not, strictly speaking, a Queen Anne building, but it comes under the same class, perhaps better termed "Free Classic." But if the smoke makes free in these Classical houses, so it does in the severe Gothic ones, and it is to one of the most severe, and I may say beautiful, modern examples

lately built that I think we must turn for a lesson in the artistic treatment of blowers. I refer to Mr. William Burges' house at Holland-park, Kensington. Here in the library, as in all the principal rooms, hooded mantels over open fireplaces with dog grates are employed. All these hoods are most beautifully carved and delicately painted in gold and colours so that the least escape of smoke would at once spoil much of the elaborate decorations. Fortunately, before any damage was done effective means were taken to prevent the escape of smoke by the insertion of a blower, which consists simply of a piece of plate glass some six or eight inches deep, and supported by an iron bar on the lower edge. This has the advantage of not obscuring the fire and yet preserves all the advantages of an ordinary blower. I think Mr. Burges' practical idea is worthy of imitation, even by those who, like myself, are tainted with a love for the style called Queen Anne for one's fireside.—I am, &c.,
Feb. 7, 1879.

AN OLD TEE SQUARE.

THE METHLEY SCHOOL BOARD v. GOUGH AND PATTINSON.

SIR,—As your report of the above action, probably drawn from a local source where feeling would not unnaturally be with the board, is calculated not only to prove injurious to me, but also to be a serious annoyance to other gentlemen in the profession bearing the same name, I should feel obliged if you would, in justice to them as well as to myself, allow me to make a few remarks. In the first place, I would state that the schools were completed in April, 1877, and the Board were so well satisfied with them, that they paid the contractors half the balance due at two months after the completion instead of four months as arranged in the contract. Some time after completion, I sent in my account, and for a long time no notice whatever was taken of it. After a period of about three months, I heard that the Board considered 5 per cent. should cover all charges; to this I demurred, showing them that no such arrangement was ever made, and sending them the Rules of the Institute to prove to them that I had only charged what was fair and reasonable, or rather that I had charged considerably less than what was customary. A long correspondence ensued, and I made every effort I could to avoid litigation, suggesting arbitration, &c., and lastly agreeing to make an abatement rather than have any further dispute. All efforts to get paid, however, failed, and finally, some twelve months after the schools were completed and occupied, I was compelled to bring an action to recover my costs. Up to this time no single complaint of any kind whatever had been made either to me, or to the contractors; but in their statement of defence, I found for the first time careless and neglect on my part were alleged, and two hundred pounds were claimed as damages. For particulars of this I had to take out summonses, when after much trouble, I, at last, found part of my neglect was in not sweeping chimneys, repairing harmonium, &c., &c., things not in the contract, and not a single item of which they could substantiate. This counter-claim was at last withdrawn, and a fresh action commenced for breach of contract and neglect, the contractors being also made parties to this suit, and two thousand pounds damages claimed. This action is the one reported by you. The alleged breaches of contract were the use of Lias lime instead of Selenitic, facing bricks, slating, and flooring of inferior quality. With regard to the lime, the Board had already allowed the contractors an extra, although the same was not awarded by me, yet it was claimed by the builders as they had used it in the proportion of two-and-a-half of sand to one of lime, instead of five to one as specified; the other items the witnesses for the Board failed to prove, and Mr. J. P. Seddon, and Mr. T. Thornton Green, a surveyor to the London School Board, and also to the Metropolitan Board of Works, after carefully inspecting the schools, gave such conclusive evidence that the works had been carefully carried out, and that any slight variations from the contract had been made entirely in the interests of the Board, that after Lord Justice Brett had summed up, the Jury found a verdict in my favour, and judgment was given accordingly. Immediately after this the Board withdrew their defence to my action for payment for professional services, agreeing to pay all costs. Such being the facts, I am content to leave your readers to form their own conclusions. My reputation is dear to me, and although

this letter has been necessarily a long one, I trust to your sense of honour and justice to publish it. Shorthand notes of the entire case were taken, and I shall be happy to submit them to you for publication or otherwise, if desired. The matter is certainly one of importance to the profession, and Lord Justice Brett's summing up defines to a great extent, and very clearly, the legal responsibilities of architects, upon which subject there has lately been so much correspondence.—I am, &c.,

HUGH ROBERT GOUGH.

MATLOCK CHAPEL COMPETITION.

SIR,—It might be inferred from the letter of "One of the Unsuccessful 85" in your last week's paper, and also from the last paragraph of your notice of the above, that this competition had been decided in a very unfair manner. So far as we have been concerned in the matter, we have not departed in the least from the bounds of honourable competition, and whatever urgency the committee have used in making their selection, it appears to us that your correspondent is more clever even than they in that respect, seeing that he can determine in far less time than they used in making their selection, that there were twenty or thirty superior designs to ours. No doubt he was pretty certain about the merits of one at least in the number, and had that been chosen we should have heard nothing from him of either urgency or unfairness.—We are, &c.,

DIXON AND MOXON.

SEVENTEENTH CENTURY HOUSE AT DERBY.

SIR,—I notice in your number of the BUILDING NEWS for Feb. 14th, a sketch of an old house built early in the 17th century, at Derby. May I be allowed to correct a mistake which occurs in the short notice describing the house, stating that formerly it had one more bay than was taken down to make room for the street at the side? Formerly, and within my recollection, it had three more bays and gables, making a frontage of five in all, and the ground and first-floor rooms were the entire length of the front. These three bays were pulled down by my grandfather to make room for the street, which entirely spoilt the house and grounds, which used to cover several acres. Several generations of my people have lived in this "Wardwick House," which was my home in early life; and I can well remember the large rooms with their fireplaces like a small room attached, and the beautiful oak panelling. Perhaps you may think fit to correct the mistake in your next number.—I am, &c.,

F. J.

FRITHSTOOL.—CHURCH BELLS.

SIR,—Your definition of "frithstool" reminds me that there is a good and little-known example of the frithstool in Chewton Mendip Church. It is a stone seat cut in the thickness of the wall, beneath a window on the north side of the sacristy. Mr. Parker mentions two examples only, one at Hexham and the other at Beverley, and both are on the north side of the chancel. As I am writing may I ask if any one can tell me at about what period church bells were first hung to wheels, and raised and rung in peals?—I am, &c., R. S. PHILPOT.

Chewton Mendip Vicarage, Bath, Feb. 3.

THE R. S. A. EXHIBITION.

SIR,—The allusion to design for N. P. Church, Dundee, in your critique on R. S. A. Exhibition, is inaccurate in two important particulars. First, the church has no "nave and transepts" in the ordinary acceptance of the terms, and 2nd, the "inevitable tower and spire" are only conspicuous by their absence.

A tower there is, but it is crowned by a lead-covered elongated dome.

As the value of critical remarks depends in some measure on absolute accuracy of description, may I trust to your insertion of this correction?—I am, &c.,

G. S. AITKEN, Dundee.

MR. T. ROGER SMITH has just concluded a short course of lectures on "Architecture" at the School of Military Engineering at Chatham. He has illustrated these by a method which is somewhat novel, for in addition to the usual diagrams, "lantern illustrations" have been employed. That is to say, photographs of buildings have been magnified and projected on a screen by the electric light, with the aid of a large magic lantern. Upwards of 150 buildings, or parts of buildings, have been by this means shown with great brilliancy, as well as perfect accuracy; and the experiment has proved a perfect success.

Intercommunication.

QUESTIONS.

[5685].—**Water-Colour Drawings.**—Will some architectural colourist kindly give me advice as to whether "body colour drawing" (mixing of Chinese white with pigments), or "transparent colour drawing," is preferable for architectural work, perspectives, &c. I see that Mr. Ruskin, in his "Elements of Drawing," pp. 201, strongly advocates "body colour."—Y. Z.

[5686].—**Bells.**—Will some reader show the method of calculating the number of changes that can be rung on various peals, and what is the number of changes on four bells?—BELFAY.

[5687].—**Shop Fronts.**—Will some reader give a few hand sketches showing the details for hoxing to story part for weights, arrangement for revolving shutters, and fixing stall board, framing, and sashes?—IMPROVER.

[5688].—**Skittles.**—What is the best foundation to put under an oak floor to deaden the jar as much as possible, and to keep the joists from sinking?—ISQUARN.

[5689].—**Marble.**—The imparting through these columns of a really efficacious recipe for readily restoring the gloss to a black marble mantelshelf, to which French polish or furniture paste (or both) has been applied, would greatly oblige—MARMO.

[5690].—**Gutters.**—The opinions of correspondents are solicited as to the relative advantages of wood and cast iron eaves gutters with special reference to suitability, cost, durability, or any other grounds. What are the special advantages and disadvantages of each kind? Reference to any source of information would be acceptable.—W. J.

[5691].—**Culverts.**—What is the method of determining the size a culvert should be to carry a burn through an embankment? How much larger in area should the culvert be than the sectional area of the ordinary stream to allow for storm-water, floods, &c.?—W. J.

[5692].—**Girders.**—On page 65, "Tredgold" (1875 edition) gives this rule for finding the breadth of girders when the depth and length are known

$$L^2 \text{ in ft. } \times W \text{ in lbs. } \times .011 \text{ (which is (a.) in Table VII.)} \\ D^3 \\ \text{In applying this to the following case where the girders are 8 ft. from centre and have a 20 ft. bearing, being 14 in. deep, and to carry 13 cwt. per ft. sup., the result comes out} \\ \frac{(400 \times 31360 \times .011)}{2744} = 50.285 \text{ inches.}$$

Will some of your numerous readers be good enough to point out what is wrong in the above? And tell me if there is a better way than this of adapting the formula on p. 14 of Hunt's Handbook $(W = C \frac{b d^2}{L})$ substituting

$$x \text{ for } b \quad W = \frac{x d^2}{L} \quad \text{or } x = \left\{ \frac{W}{C \times \frac{d^2}{L}} \right\} \div C \\ \frac{W = 8 \times 20 \times 13 \times 7}{\text{divided by 2 for dist. load}} \left\{ \begin{array}{l} \text{on p. 17} \\ \text{C = 4 for fir. (p. 16)} \\ \text{less } \frac{1}{2} \text{ as advised on foot note, p. 16} \end{array} \right\} = 980 \text{ cwt.} \\ \text{Then } x = \left\{ \frac{980}{\frac{3 \times 14 \times 14}{20}} \right\} \div 3 = 11 \frac{1}{2} \text{ inches.}$$

STUDENT.

[5693].—**Turned Newels.**—Are turned newels to staircases fashionable at the present time? I seldom see one in an architect's drawings, or in the architectural journals. Most of them seem to be square hand-wrought moulded newels. Would some kind friend who really knows what is now generally used give a sketch of newel and outer string suitable for an ordinary villa or good mechanic's cottage, and oblige an old-fashioned staircase hand who is now a

COUNTRY PRACTITIONER.

REPLIES.

[5667].—**Portland Cement.**—To Smeaton we must accord the honour of having introduced this cement. He was the first to investigate scientifically the hydraulicity of certain limestones, and his experiments for Eddystone lighthouse with Aberthaw lime and tarrus and puzzolana, resulted, I believe, in the origin of the name through the cement resembling so closely Portland stone. From Vitruvius downwards little was known respecting the property of hydraulicity till Smeaton showed how to make limestone that should stand and harden under water. Portland cement subsequently began to be made with river mud, but it must be remembered that the same cement can be obtained from many other materials besides those of chalk and river clays.—G. H. G.

[5670].—**Laundry Drying Closet.**—I have seen a drying room heated by Hearn and Co., of Liverpool, with small wrought iron pipes in, bore; the heat attained was 170° and it worked in a very satisfactory way, and was very little trouble, only requiring a pint of water once a month. I think "Bar of Soap" would find this apparatus to be all he could desire, and in time it would pay for itself it is so simple and economical.—J. A. BRICK.

[5671].—**Storing Rain Water.**—Taking the rainfall to be 18 in., 20,400 odd gallons would fall on the given surface in the course of a year, allowing 56 gals. per day. Authorities consider a four months' supply should be provided, and this would require a tank containing 1,680 cubic ft. or about 12' 0" x 12' 0" x 7' 6" inside dimension. The variable nature of the supply precludes the possibility of regulating the size of the receiver more nearly.—A. L.

[5672].—**Gilding Plaster Casts.**—A gilder will know to treat it. Gold will keep its colour and last a long time. Silver exposed to the air will speedily tarnish and become black.—JOHN ALGAR.

[5673].—**Fir.**—Make acquaintance with the working foreman of the nearest timber yard, spend an hour with him every morning before office hours commence, for three weeks or a month; you will then obtain more prac-

tical knowledge on the subject than by any other means.—G. H.

[5673].—**Fir.**—There appears to be nothing inconsistent or unfair in giving the questions referred to, as the different kinds of fir timber are easily recognised when worked up. White fir or spruce (or white deal) has a uniformly whitish colour from the comparative absence of resinous matter in the pores, the rings being less distinctly marked than in the red fir. The knots are of a dark brown colour, hard, brittle, and apt to get loose. There is no difference of colour between the sap and heartwood. Red fir or pine, or yellow deal, has the hard and soft rings very distinctly marked, giving the surface a honey-combed colour with reddish streaks, and gives off a strong resinous smell when being worked. The knots are of a bright red colour, and not so hard as in the white timber. The sap wood is usually darker than the heartwood, assuming a greenish hue on being exposed. Baltic red fir is heavier, and the balks run larger than the white fir. Yellow pine (American), has a brownish colour with small black streaks on the surface. It is lighter, straighter in the grain, freer from knots, and more easily worked than the yellow deal. Pitch pine has a reddish appearance, the pores being filled with resinous matter, giving off a strong smell. It is a very heavy timber, with a sticky feel, which renders it difficult to work.—C. W.

[5674].—**Ordnance Datum.**—By obtaining a sheet of the Ordnance Survey having one of the known bench marks on it, "Beta" would obtain the figures for it, which could then be used to bring his figures to ordnance datum. The process seems so simple that I am afraid I have mistaken the meaning of the writer.—A. L.

[5676].—**Orders of Architecture.**—No modern work of a similar kind to Nicholson's has been published giving the subdivisions of the "Order" at the side. There is a little treatise by Leeds in Weale's series; but "Nicholson's Principles of Architecture" would meet "C. B. C.'s" wants, and second-hand copies may still be obtained. Of course there is Gwilt's Encyclopædia, but the Orders are drawn small.—G. H. G.

[5677].—**Body Colour.**—I presume "One in the dark" is writing of water-colours. My own practice has been to avoid body colours in water-colour drawings, and to use as little of it as possible, and that only in the touches of foreground. To obviate maddiness and unevenness, however, the rules are simple. Select paper with a good tooth, stretch it on a board or frame, well sponging the surface before commencing to colour; i.e., the board a little when laying on your large washes of colour; begin working at the top edge on the left hand with a fully charged brush, and never work backwards or retouch. The last is the main rule to observe in colouring large surfaces, and is indeed the secret of transparent tinting. It is best to begin with the cooler colours.—G. H. G.

[5677].—**Body Colour.**—It is very likely a fault in the plaster or wall. The most effectual way is to give the work a coat of paint and a coat of size before colouring.—JOHN ALGAR.

[5678].—**Painting Cement.**—After 25 years' experience, I have never known anything effectual in preventing wet coming through a painted wall or cornice, let the material be what it may, although many things have been advertised from time to time for the purpose. Water must evaporate, and on the same principle that a boiler will burst that has no safety valve, so will water force its way through any material that confines it. Cover your cornice with lead, and draw off your plinth.—JOHN ALGAR.

[5678].—**Painting Cement.**—Use the silicate paint after removing the old paint.—ARCHITECT.

[5680].—**Clerk of Works Salary.**—An architect who employs a clerk of works, and pays his salary by request of client, is certainly not legally entitled to any profit save interest on the money advanced.—G.

[5681].—**Voluntary Architectural Examinations.**—The instructions appear vague. By "an outline of certain characteristics of the principal historical styles of architecture," they would include Egyptian, Assyrian, Greek, Roman, Byzantine, Romanesque, Gothic, and Renaissance, as the leading; the object of the course is to obtain the candidate's knowledge of leading peculiarities of style. The next requirement means, if I understand it right, that the student should describe in more detail one of these styles, as Greek or Gothic. He may confine himself to English or French Gothic, or to one particular period; this is clearly optional with the candidate. The meaning of the clause, "a specimen detail drawing to an inch scale of the work in each trade, and an equal number of full-size drawings to correspond," is certainly not so clear. The number of trades to be represented would include all those engaged in ordinary building, which I need not say includes the bricklayer, mason, carpenter, joiner, slater, plasterer, smith, ironmonger, plumber, decorator. "Each" in the above clause is, of course, to be interpreted as meaning drawings of all the trades.—G. H. G.

[5682].—**Cubic Space.**—"Hexagon" will find his query answered if he turns to the Commonplace Column under this head. For dwellings, 600 feet cube is the least, though for dormitories it should be at least 800 feet per head. For hospitals, 800 to 1200 cubic feet are allowed per man, the larger quantity being necessary for dormitories in acute cases.—G. H. G.

[5684].—**Fixing Tiles.**—The tiles will not come off again if "Calor" will have flat iron bars built into brickwork at back, upright with ends turned in; from these bars, small projecting pins, with a thread worked on end; these to come through at the corners of tiles, which might be filed off if found necessary, to allow the pins to pass, and still keep a close joint. A brass or steel boss can then be screwed on to each pin, which will each be holding the corners of four tiles apiece. The distance apart for bars and pins to be decided by the size of the tiles, and length of pins by thickness of same.—LXXXIV.

At a vestry meeting held at St. Peter Mancroft, Norwich, on Thursday week, it was decided to take in hand at once the repair and restoration of this fine 15th century church, the largest in the city, and a committee was appointed to carry out the work.

Our Office Table.

MESSRS. RANSOMES and RAPIER, engineers, of London and Ipswich, have published a pamphlet, in which they draw attention to the defects of narrow rails for tramways, and the growing nuisance they have caused in the London suburbs. What the authors say, as regards the inconvenience of driving ordinary vehicles over tram lines cannot be called in question; but we think the greatest nuisance arises not so much from trying to keep on the metals as from attempting to avoid the ruts or grooves between the pitching and the rails. To obviate the narrow tramway, Messrs. Ransomes and Rapier propose wider rails, 10 to 3in. broad, which, it is believed will allow anyone to enjoy the easy motion. "One wheel hugs the groove, but does not enter, and the other runs on some part of the 10in. face on the opposite side." This wide tramway has been in use seven years under very heavy traffic, it is alleged, and is found to be convenient, both for ordinary as well as tramway traffic. In Glasgow, the plan is found to answer, and is said not to have cost 6d. for repairs for 7 years. Looking at the drawings of the "Permanent" Tramway, we find they are made of cast-iron T-shaped, in section, the groove being in the centre. They are cast in short lengths, the surface being "chilled." The hollow underneath is filled up with concrete, and the blocks are laid upon concrete beds 1ft. 10in. wide by 6in. deep. They are, in fact, continuous blocks of cement concrete with chilled cast-iron surfaces, thoroughly rigid, and fastened by fish plates and bolts. The authors lay great stress upon the value of rigid tramways, and allude to the continual movement of the ordinary rails which rise and fall, and by this action are constantly sucking in and squirting out surface water, which action tends to rot the sleepers and produce speedy decay by the abrasion. To prevent the wide faces becoming slippery to the horses' feet, small grooves are formed along both edges at short intervals. We think the proposed method of laying has decided advantages in these respects, and we prefer the section of rail shown with flanges below tailing under the stones, as obviating the evil we have so frequently pointed out in our pages.

ANOTHER corporation fight has taken place over the building of public offices for Southampton. We commented not long since upon the attempt to spend a large sum of money in the remodelling of an old structure long since displaced by the growth of the town from its true business centre, and last Wednesday week the council, by an insignificant majority, decided not to throw away £7,000 of the ratepayers' money on such a scheme. So far this decision is satisfactory. It appears that Mr. Lemon, the consulting engineer, had instructions to prepare plans for rearranging the present building and adding to it, at a cost not exceeding £3,000. Mr. Lemon found this sum quite inadequate; the estimate came to £7,000, and from this amount the sum of £2,000 was

ultimately struck off in respect of decoration. Now £2,000 is a large sum to strike off for such a purpose, and would go a long way in acquiring a better site. From what we can gather the council are indebted to their engineer a considerable sum for his services, which might have been spent on premiums to obtain the best talent of the country. As regards the cost of a town hall and offices, an expenditure of £20,000 would be sufficient, if we consider the requirements and estimated cost of the buildings for a similar purpose erected at Leeds, Wakefield, Barrow-in-Furness, and other places. The Southampton town council will, no doubt, see that a public competition from the whole profession is the best and least expensive course to pursue, and, if liberal premiums are offered and fair dealing is guaranteed, they will in due time get a building worthy of the town.

THE annual meeting of the subscribers to the Birmingham School of Art was held on Wednesday afternoon, at the Midland Institute, under the presidency of Mr. William Morris. In moving the adoption of the report, the chairman said he believed that a very decided improvement had taken place during the past year in the work of the students. The report having been adopted, Mr. Morris was re-elected president, and on the motion of Mr. J. H. Chamberlain, it was decided that the nomination of students by subscribers should be discontinued. In the evening the president distributed the prizes to the successful students in the town-hall, and delivered an exceedingly interesting address, to which we shall probably refer at greater length next week, on the progress of art at home and abroad.

THE Sowerby Bridge Local Board have just erected baths, public offices, and abattoirs, the plans of which are before us. The ground plan of site is oblong, and some ingenuity has been exercised in the management of the ground level and the steep slope to the river. A swimming bath 6ft. by 21ft., surrounded by paths and dressing boxes, is placed in the rear close to the river, the entrance to it being by a long passage with steps, which also gives access to a smaller swimming bath for boys, and a series of private baths. The arrangement of entrance is well managed. There it also a washing and drying room, below which is the boiler house. On one side of the bath entrances are the public offices, comprising offices for the surveyor, accountant, and collectors, with a board-room over. The swimming baths are roofed with iron, the principals being trussed and these carry wood purlins. A ridge ventilator is provided over the large one which is lighted by windows facing the river; the other baths have skylights. On the other side of the site is a range of buildings arranged as cattle pens, and slaughterhouse. The fall of ground has here been made the most of by forming the pens below the roadway to the abattoir. A fire-engine station is also provided at the entrance. Mr. J. H. Smedhurst, the Surveyor of the Local Board, prepared the plans.

It may not be generally known that the Local Government Board have certain rules in respect of pipe-laying, among which we find that street

mains are recommended to be of cast iron not less than 3in. internal diameter, and to be well varnished; that lead is not advised to be used with soft water in service pipes or cisterns, but that wrought-iron tubes with screw joints may be employed for house service; that house-taps should have screw joints of the "screw down" kind; and that in wrought-iron pipes double screw joints at convenient places should be inserted to allow of easy repair or the removal of a pipe. These are useful precautions, though not often consulted. There is no doubt wrought-iron pipes are cheaper, stronger, and better than lead. In towns iron and lead pipes should be protected from the injurious action of some soils, and for this purpose a lining of asphalt, Portland lime concrete, or sand may be employed. A fall of 5ft. per mile is found sufficient for a conduit of 2ft. diameter, and for less falls larger diameters should be used. The New River conduit is about 1 in 10,000. The suggestions as to tanks of cast iron are useful. The bottom must be well supported and the sides securely stayed. The tie-rods should be made to pass through the plates and be secured by washers on the outside, not to internal irons. In all iron tank work cleaning and painting should be done once a year: neglect of this has caused many tanks to burst by the corrosion of bolts and tie-rods. Iron tanks for houses should not be exposed to the action of the sun, but clothed with boards lined with felt.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of FEVERS, EILLOUSNESS, SMALL-POX, SKIN DISEASES, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—[ADVT.]

CHIPS:

In our description last week of the National Provincial Bank of England at Sunderland, accompanying the illustration, we omitted to state that Messrs. Bellman and Ivey fixed there four large Scagliola columns, in Rossi-de-Levante, with polished white moulded capitals. The building necessitated the erection of iron stanchions within the columns; these were first placed in position, and the Scagliola columns subsequently sent from London and fixed round without showing joint.

A valuable collection of local geological specimens, formerly belonging to the late Professor Harkness, F.R.S., has been presented to the museum at Carlisle.

Mr. F. J. Francis asks us to correct an error which occurs in our report of his paper on "Hotels and Restaurants." We described Crosby Hall as having been altered by Messrs. Francis and Saunders—it should have been stated by Messrs. Francis only.

On Monday week, at a meeting of the Royal Scottish Academy, held in Edinburgh, Mr. James Cassie and Mr. Robert Gavin were elected Academicians.

The new West Ham and Stratford Dispensary, in West Ham-lane, Stratford, E., was opened on Friday week. Mr. J. T. Newman was the architect, and Messrs. Hooking Bros. were the contractors. The cost has been nearly £4,000.

Plans have been approved by the Bradford Church Building Society for a new church, proposed to be erected at Manningham, at a cost of £8,000.

THE BUILDING NEWS.

LONDON, FRIDAY, FEBRUARY 28, 1879.

ART, ITS AIMS AND OBJECTS.

AT the distribution of prizes, last week, in connection with the School of Art, at Birmingham, the President, Mr. W. Morris, delivered an interesting address, which, though it must to a considerable extent have been delivered over the heads of its hearers, yet contained some salutary truths. The Birmingham School of Art is an influential Society aiming at a wider art education than that usually fostered by a mere local school; it stands first in the list of schools of the second grade, and in the national competition it has always maintained a creditable position. This being the case, we cannot be surprised that the president took a rather extended view of its work and prospects, and that the aim and objects of art, were looked upon from a somewhat lofty standpoint. Allowing that the circumstances called for a more than ordinary comprehension on the subject, we cannot but think Mr. Morris's address dealt too much in hyperbole, and too little with the practical in art, before so practical an audience as that gathered before him in the Midland Institute at Birmingham. Parts of the address must, we fear, have been rather unintelligible to many. The burden of it was a protest against the aimlessness of art, and the commercial spirit of modern life. History, morality, and politics were strained to interpret some very easily explained facts, and the speaker seems to have been carried away occasionally by his enthusiasm into rhapsody. We can heartily sympathise with the desire of Mr. Morris to raise the tone of art, to minimise the amount of unhappy and misdirected labour in the world. We agree with him that the chief duty of civilisation should be to set about making labour happy for all, rather than to encourage art and energy for warfare. We are ready to admit, too, that a large proportion of the work done is dishonest and degrading; that is to say, tending to make some rich at the cost of the slavery of others; or, in a word, that the ultimate end of true art is lost. But these sentiments are not new. Bentham and Hume, Mill, and other moral and political economists have all laboured in the same field in the effort of reforming and improving human life, and directing energy, and while they have indicated the way, Mr. Morris has only pointed out the effect as regards one branch of industry. The virtues of "honesty and simplicity of life" doubtless lie at the foundation of all true and pleasure-giving art, and the problem is how to secure these aims. According to Mr. Morris, this degradation of art has arisen mainly from the evasion of plain duties, from luxury, and the competitive spirit of the age; but it is necessary to point out here that these things are to a certain extent inevitable to our transitory stage of modern civilisation; that the present age is one in which the commercial activity is the greatest, and that it is quite as impossible to live now the simple life of the Plantagenet village craftsman, as it is to reach the Utopian millennium of art which Mr. Morris places before our vision. We are told, "From Ispahan to Northumberland there is no building built between the seventh and seventeenth centuries that does not show the influence of the labour of oppressed and neglected herds of men. No one, indeed, rose high above his fellows. There was no Plato, or Shakespeare, or Michael Angelo amongst them, yet, scattered as it was among many men, how strong

their thought was! how long it abided! how far it travelled! And so it was ever through all those days when art was vigorous and progressive. Who can say how little we should know of many periods but for their art? History (so-called) has remembered the kings and warriors because they destroyed; art has remembered the people because they created." Very true, indeed, is the assertion that a century of the Byzantine empire gives us a weary chronicle of "pedants, tyrants, and tax-gatherers to whom the terrible chain which long-dead Rome once forged still gave the power of cheating people into thinking that they were necessary lords of the world." Truly history has left a tale of "languor, and the evil deeds of kings and scoundrels"; but that there were others of whom history does not speak who have left us evidence of honest labour done in grief and joy. In the records of art no one can gainsay the fact that art, during the mediæval period, was greatest when the individual artist was nothing, whereas it is quite as incontrovertible that art has declined as the artist's power has become more personal. All that we know is that it is an unalterable condition of history rightly read, only to be explained by the creation of the multifarious activities of a more complex state of society. Before we can make the art workman's labour less dreary and degrading we must remove the obstructions and restrictions under which he lives. Mr. Morris admits there is "an apparent external progress in some ways; that in England painters of pictures have grown, are more conscientious in their work, and have expressed a sense of beauty the world has not seen for the last 300 years." He admits also that in architecture and the arts that attend it, there has been great improvement in England, though other countries have done little more than stand still. "These improvements have, it is said, concerned comparatively few people, the mass of our population not being in the least touched by them, so that the great bulk of our architecture—the art which most depends on the taste of the people at large—grows worse and worse every day. You must go to London if you don't believe it." Mr. Morris, whatever his qualifications to speak of art generally, certainly does not in his opinion as regards architecture agree with the bulk of intelligent or discerning critics concerning it. It has been admitted by every authority capable of forming an opinion that architecture has made rapid strides during the last quarter of a century. We do not point to any particular phase of it, or to any ruling fashion, but to the general appreciation of truthful construction and honest expression it has been the witness of. If we mistake not, the opinion advanced by Mr. Morris is shared by others who deny to modern architects the right to create new, or to restore old, buildings, but who at the same time are always uttering a lament at the national decadence of architecture. Such pessimism, to say the least, is not healthful or hopeful, and the sooner we accept, in a true spirit, our present position as the only one possible for our age, the more likely it is we shall make an advance. We note that the president extends the progressive period of architecture to the seventeenth century—two centuries later than is usually accorded; but surely, if we can acknowledge the building of that period, we may include our own century? "Though many of us love architecture dearly," he observes, "I believe that it helps the healthfulness of body and soul to live among beautiful things, we of big towns are mostly compelled to live in houses which have become a by-word of contempt for their ugliness and inconvenience. The stream of civilisation is against us, and we cannot battle against it." We will not dispute the

truth of the allegation, but is it possible for any art reformer to give us better houses till the people are prepared to receive the lessons of art? Passing to pattern design, the speaker called attention to the deterioration of art in the East, which has always been held in such high esteem among ourselves. In short, the address pointed to another instance of the falling away of the art instinct, which nearly always succeeds conquest and civilising agencies. In India it is said Englishmen in their short-sightedness are actively destroying the sources of that education we are attempting to promote, in jewellery, metal-work, pottery, calico printing, brocade-weaving, carpet-making; all the famous and historical arts of the peninsula have been thrust aside for the advantage of any paltry scrap of so-called commerce. The "art manufactures" of India are beginning to deteriorate, and the "conquered races, in their hopelessness, are everywhere giving up the genuine practice of their own arts, which we have loudly proclaimed are founded on the truest principles." The speaker alluded to the way Government is furthering this deterioration by manufacturing cheap Indian carpets in the Indian gaols. Mr. Morris does not say this is a bad thing if properly managed, but complains that it will make wares cheap, and that it is this desire that is destroying Indian manufacture. In fact, Eastern art is dead, and "the commerce of modern civilisation" is declared to have slain it. "Obvious as is the surface improvement in the arts within the last few years among ourselves," the president said, "there is something wrong about the root of the plant to exult over the bursting of its February buds."

But what is the remedy proposed for all this? Much there is that we admit in this long wail of lamentation; civilisation is against art we are told more than once. Great men of art have but a narrow circle that can understand them, and are utterly unknown to the great mass of people. Art, in short, has become a too delicate thing for the people; many honest and intelligent men eager for human progress, yet anti-artistic, believe art to be intended only for the few: hence their treating it lightly. Mr. Morris attempts justly to disabuse this idea; he shows that all the treasured art we collect at Kensington and our museums is nothing extravagant, but represents the common household goods of past times. The things we value were common things in their own day, no rarities; no great artist drew the designs for them, highly paid, daintily fed, or carefully housed; but they were made by "common fellows," as the phrase goes, in the common course of daily labour. Their labour was not irksome. Take, again, the treasures of architecture which we study so carefully—how were they made? The village churches were designed not by the great architect carefully kept for the purpose and guarded from troubles, but by the monk, the ploughman's brother, the village carpenter or mason—"a common fellow whose everyday labour fashioned works that are to-day the wonder and despair of many a hard-working 'cultivated architect.'" This art, so careful, delicate, and inventive, may be seen in out-of-the-way hamlets, in the chest of the yeoman's wife as well as in the throne of the great Plantagenet, and it brought with it happiness and made life endurable. The president says, in short, "the thing which I understand by real art is the expression by man of his pleasure in labour. I do not believe he can be happy in his labour without expressing that happiness, and especially when he is at work on anything in which he specially excels." Only in these later days has this universal gift been rejected by man. To the "hurry of the war of the counting-house and the war of the battlefield" is attributed the irksomeness, and dishonesty, and the pleasurelessness of all our work.

The president would do away with the "toil which makes the thousand-and-one things that nobody wants, which are used merely as the counters for the competitive buying and selling falsely called commerce," and he would encourage "an art made by the people for the people—the expression of man's happiness in his labour." A little reflection will show that the loss of pleasure in the workman's labour is due to several causes beyond control. Machinery has entered into uneven competition with hand labour, driving all art manufacturers to produce their goods in the cheapest way, while competition is so great that hand labour has become a mere luxury only available for those who can pay for it. These are really the causes of the degradation Mr. Morris speaks of, but which, singularly enough, he does not once allude to. The popularisation of art is an excellent idea, but we need only say it is a work of time and education. Before our daily wants and appliances can be made artistic the public must be brought to realise the intrinsic value of art as an education of the senses, while the artist must be taught to bestow his labour less grudgingly on the commoner things of life. Again, to produce "happiness" in any work, it should not only be congenial but remunerative, though Mr. Morris does not tell us how this is to be attained under the present dispensation of labour. We cannot help thinking the Birmingham address, while it may have inspired the enthusiasm of the young student, failed to teach much by its dismal retrospect; and that the Utopia of art so graphically sketched by the president would have been a little less visionary if the plain duties of the British working man and student of art of the nineteenth century had been more clearly defined.

OUTLINE AND COLOUR AS ILLUSTRATED IN THE DRAWINGS OF THE OLD MASTERS.

A PART from the actual subjects of the works themselves, the sketch studies of Raphael, Da Vinci, Michael Angelo, and other masters now on view at Burlington House and the Grosvenor Gallery, have some particular points of value for the architect and decorative artist. In the first place, they entirely run counter to the ordinary ideas of modern artists and teachers of art by the want of finish and the lack of laboured execution they display. It is a common error nowadays to estimate the value of a work of art by the amount of mechanical labour bestowed upon it, by that appearance of painstaking care in very little detail, as if the artist were successful in proportion to the number of lines or touches he had crowded on the paper. Of course, this is a vulgar error, and we may say, as a rule, that the merits of a work of art of every kind are almost directly in proportion to the visible ease and facility of the artist's expression. To those who have any doubt about this we commend the collection of studies in the galleries of drawings above referred to. We may, for example, refer to the gradation of line and tone perceivable in the inimitable sketch landscapes of Canaletto, or the figure compositions of Raphael, Parmigiano, or Carracci. We observe nothing like finished features, details of dress, or half-tints, certainly nothing approaching a finished background; the lines of the principal figures are sketched in vigorously, in total forgetfulness of those in receding parts or planes of the picture, yet in perfect accord and balance with them; there is never a crowding or confused assemblage of figures jostling one another, and detracting from the chief theme, and no lesson is more forcibly taught us than this one of subordination of line and manipulation to the central idea of the study. In the "Study of a Tree," by Annibale

Carracci, in Gallery VII., the artist has by a few well-chosen and vigorous strokes of his pen, aided by bistre wash, produced an impression more telling in its completeness than another artist's work who had taken the pains to mark every spray or group of foliage with the minuteness of an etcher. Again, let us take the study by Parmigiano, "Christ and His Disciples Worshipped by a Crowd of People." Here the prominent figures are sketched with a power of grouping and dignity worthy the master. Although there is a crowd, there is no sense of confusion, and every line and touch of tinting throws up in marvellous perspicuity the idea uppermost in the artist's mind. The drawing is washed with bistre and touched with white—a mode of sketching very effective and expressive, and largely made use of by the cinque-centists. In Michael Angelo's "Figure of the Dawn: Tomb of Lorenzo de Medici," there is more finish, the drawing is executed with silver point, yet we find in it rather the delicacy and grace of ease than of laboured execution. The same great master's copy of portion of the "Last Judgment," in the Sistine Chapel, is another model of execution. A vigour of thought seems to struggle through the mere hand-work of lines in black chalk; as we witness quite as forcibly in his study of "Three of the Labours of Hercules"—a masterpiece of action in drawing. Equally remarkable is the pen and bistre sketch by F. Baroccio of the "Assumption," and some of the studies of Giulio Romano. There is in nearly all the masterpieces of composition a predominant idea or attitude that is at once perceived, and we are never left in doubt as to the meaning or movement sought to be conveyed by the artist. A few lines convey the expression of face, attitudes, and draperies, while degrees of solidity are expressed by skilful washes of colour. It has been remarked by an able French critic that "drawing itself is nothing but the immediate result of the differences of colour; the ideal line which bounds coloured surfaces." We have clearly in this definition the real value of lines as a mode of art expression; we must regard them chiefly as the contours or boundaries of surfaces and masses than as essential to art representation. Prudhon, it is said, instead of drawing his external bounding lines like other artists, began with his masses of light and shade. He commenced, in short, by modelling the forms instead of defining their contours, and in this respect he followed the true theory. M. Ingres also began the internal modelling of his figures, and afterwards marked their outlines. The advantage of this mode is that it makes the artist more careful of the gradations of colour, light, and shadow; the modelling and relief of his figures become the principal aim. The value of giving painters models is therefore evident; the old masters were taught figure drawing by this method, and if our artists were also more frequently adepts at copying from the round, the better it would be for art. In one direction, that of *chiaroscuro*, or the arrangement of lights and shadows, the sketches and studies of the old masters are significant. How the figures of Rembrandt and Raphael stand out!—there is no rigid contour apparent, no difference of mere colour, so much as variation in the amount of light thrown upon the different surfaces or figures. It may be called in fact the art of modelling on the flat. It gives that indication of relief which is the chief value in a picture or composition, and in short *chiaroscuro* constitutes the painter's power of modelling, so to speak, the various parts of his picture to produce a satisfactory whole. Each object or figure should have its own degree of relief, and these in turn should be placed in their proper planes or relations by the same agency of light and shadow. No artist will dispute these principles, and they

lead us to speak of the importance of that class of works in which light and shade in its various and subtle degrees take the place of colours. The term "black and white" aptly, though perhaps roughly, designates our meaning.

It is well known that with some of the greatest painters the rigid linear contour was lost in surroundings; so it was with Murillo and Correggio, so with Rubens and Rembrandt. Varied relief and appearance of movement is the result of this practice, while the accentuation of outline, as we see in the pictures of Ingres and many modern artists, at once destroys apparent depth and reduces every figure and object to a dull flatness. It must not be understood from these remarks that we undervalue the importance of outline, but our object has been mainly to show that in composition and figure-subjects contour is of secondary importance to modelling, light, and shade. There is no absolute line in nature.

The first sketches of the great masters, as we see them at Burlington House, were remarkably free. They were the result of a masterly disposition. The figures seem to be thrown together under groups or masses, never in higgledy-piggledy confusion. Raphael, Michael Angelo, Da Vinci, Delacroix saw things in their *ensemble*, and each line and stroke of pencil or colour had a generalising boldness at once bringing out and relieving the figures and expressing their movement. If we attentively examine the black and white studies of these masters, we at once see the *rationale* of the process: they began by modelling in more or less broad washes, building up their figures in proportionate quantities of light and shadow till the outline was nothing more than the finish. In all their work "detail" had a subordinate place; they never began by drawing a head here, an arm there, and so on, but with the instinctive flash of genius they portrayed the total impression, filling up afterwards. Every touch of colour or shade had, however, a form and meaning.

Lastly, we find that monochromes were favourite modes of execution. Low-toned colours, and especially browns, were the principal pigments employed, and sepia or bistre were chiefly used. Mixtures of brown and cool greys add much to the effect and relief, but the whole compass of light and shade and tone was quickly realised by the heightening effect of white. It is wonderful what a variety of effects and tone may be got from black, say ivory black, and white. Every conceivable combination of grey and shadow can be produced; and the advantages of black or low-toned browns need not be enjoined here for all studies for sculptured decoration, particularly those of the architectural artist. There is a love among many of our water-colour artists for thick painting—a heavy, impasto kind of style, which seems to us to prevail among those who have the least confidence in their work. The colour is added and thickened till the drawing becomes lost. For architectural subjects transparent colouring has undoubted merits, and the aim of all skilled colourists is to produce effect with the least expenditure of colour.

LECTURES ON THE RISE AND DEVELOPMENT OF MEDIEVAL ARCHITECTURE.*

THE lectures delivered at the Royal Academy by the late Sir Gilbert Scott, R.A., just published by Mr. Murray, possess a more than transient value to the student. They are the outcome of the study and experience of an admitted master of mediæval architecture and, we may add, the most celebrated Gothic architect of the

* Lectures on the Rise and Development of Mediæval Architecture, delivered at the Royal Academy by Sir GILBERT SCOTT, R.A., F.S.A., LL.D., &c. London: John Murray.

present century. Delivered in the heyday of a professional reputation, amid the daily cares and absorbing labours of an unsurpassed practice, there is much in them that will now be read a second time with renewed interest by the architectural student and even the professional man. As many of the later lectures have been fully reported, and as several of the illustrations have already appeared in our own pages, we take it for granted that the scope and object of the work are pretty well known to our readers. In the preface to the lectures written by the late Sir Gilbert Scott, so late as the beginning of last year, it is stated that only half the lectures were delivered by him as Professor at the Royal Academy. The first seven were delivered while Professor Cockerell held the chair, but owing to his health, Sir Gilbert Scott, in conjunction with Mr. Smirke, was called upon to relieve him of this duty. The eighth, ninth, and following lectures were given after the retirement of Mr. S. Smirke. These circumstances have naturally tended to produce a somewhat disconnected series, which is pointed out by the author; but, as we can fully believe, he says they were "written with much zeal," and to his pupils and sons he accords thanks for the assistance rendered in the illustrations, which are certainly very profuse and, on the whole, highly creditable. A note to the preface acquaints the reader that many of the illustrations have been prepared from sketches and marginal references left by the author by Mr. W. Samuel Weatherley, while others have been procured from reliable sources. Perhaps the first lecture is more characteristic of Sir Gilbert Scott's mind than the later ones. He begins by enforcing the historical claims of Pointed architecture upon our study—a task for which no one better than he could have been chosen. These claims have sufficient interest, even at this time, to be recalled. The first is that Gothic architecture is the architecture of the modern, as distinguished from the ancient world; the second, that it is a style *par excellence* Christian; and lastly, that it is the native architecture of our country. These claims are discussed in a moderate and conciliatory tone. The claim that Pointed architecture is Christian is argued in a like spirit. The author acknowledges that it is not the "only Christian style which has arisen or is likely to arise, but that it has been more entirely developed under the influence of the Christian religion, and more thoroughly carries out its tone and sentiment than any other style." This is a sensible view of the case, and one which no anti-Gothicist is likely to call in question. The lecture then proceeds to the intrinsic or abstract claims of the style, and in discussing these we find the author still moderate, and not affirming anything questionable. He, of course, dwells upon the advantages of the arcuated over the trabeated system, especially the pointed arch, though he does not urge it to the detriment of other forms. The facility of the style in decorating construction; the flexibility of its forms, such as the arch and vault; its adaptability to varied climates; its power of uniting the arts of painted glass, sculpture, &c.; and the special objects of its study are pointed out with a master's hand. In the last of these remarks, he points out the danger of pursuing the study in a spirit of antiquarianism. He suggests that our own object should be art, not antiquity—useful hints, but which the author himself lived long enough to see impugned. In another part, he impresses the value of real study derived from buildings themselves, as being of more importance than facts obtained indirectly. In lectures II. and III. the rise and development of Mediæval architecture is sketched, and from these the younger student will derive a more connected account of the growth of

the style than from any other elementary work we are acquainted with. The structural process which gradually transformed the Romanesque basilica into the pointed-arched church, is clearly traced to statical and æsthetic reasons; the history of vaulting is sketched from the early barrel vault to the groined oblong bay, the works of Dr. Whewell and Professor Willis being here laid under contribution. We may remind the reader that the author repudiates the capricious origin of the pointed arch, and attributes its introduction solely to the necessity of statical construction, and chiefly to its diminished thrust; not, as asserted by some, to the necessity of obtaining arches of equal height at the side of oblong groins. In substantiation of this view, the earlier of the French Transitional churches are quoted, such as Noyon Cathedral and St. Germain des Prés; while at Canterbury also we find the wall rib round, and the wider or cross arch pointed. In fact, Sir Gilbert Scott believes the arch of this form was adopted for constructional motives, and these he classifies under statical, geometrical, and æsthetic heads—the first exemplified in wide-span arches, the second in narrow arches of oblong vaulting, &c., and the third in the harmonious combination of various arched forms. The French architects were the first who undertook the solution, and to perfect the system. Some beautiful illustrations of the apsidal chapels of St. Denis, Noyon, St. Germain des Prés, and the Cathedral of Sens (the supposed archetype of Canterbury) accompany this interesting section of the work, while excellent representations of the Choir of Ripon, Canterbury Choir, and Trinity Chapel, Chichester Cathedral, Tynemouth Abbey, and St. Cross, Hampshire, exemplify the working out of the problem in England during the so-called Transition. We cannot but admire the beautiful illustrations of Chichester Cathedral, Tynemouth Abbey, and Hexham, as representing the later works of this period, and as unique examples of architectural drawing applied to book illustration. The nave of Fountains Sir Gilbert designates as Romanesque, as also Kirkstall and Buildwas. Of another stage, called the refined Norman, the Galilee at Durham and St. Mary's Abbey, York, are instanced, though the last has decided pointed arches; while the author places St. Cross, near Winchester, as intermediate between these classes. Trinity Chapel, Canterbury, is put in the third class of the Transition or typical of the Early Pointed phase, though retaining just enough of Romanesque to distinguish it from well-developed Early English. The development of carved capitals is introduced here, and is copiously illustrated with examples. The author claims for the English Transition equal nationality with that of France, although the latter preceded the former; and he also says, what every true Gothicist must admit, that the English Transition was carried through to a style more distinctive than that of the Early Pointed of France. The lecture on the thirteenth century enters upon the full-grown Gothic, and the author seems here to expatiate with exultation on a style to which he devoted the best energies of a lifetime. Here and there he is carried away with that fervour and emotion which those who have heard him can best realise. Speaking of the classification of Mediæval architecture and the non-coincidence of the styles with the centuries, he suggests that the Norman should, roughly speaking, occupy the interval between 1075 and 1175, the Early Pointed from thence to 1275, the Middle or Decorated period from 1275 to 1375. Sir Gilbert Scott entertained a preference for the vigour and boldness of the works of the earlier part of the thirteenth century, and it must be confessed his most satisfactory works are executed in the earlier phase. His sketch of

the opening of the century is interesting; in France the secular and ecclesiastical powers had reached a high stage of development, while in England the barons and the Church, at least, were prosperous. At Canterbury the cloisters were added in the perfected style; at York the Norman transepts were rebuilt; St. Hugh at Lincoln made a pretty complete remodelling in the style; Wells underwent rebuilding; the western porch and choir of Ely were undertaken; St. Albans had its western façade, nave, and choir rebuilt; but the most complete works of the age were Salisbury Cathedral and Tintern Abbey, while numerous other buildings, as Westminster, and St. Mary's Abbey, York, were partially remodelled. Perhaps one of the most unique examples of the period is the beautiful Chapel of Nine Altars at Durham. Speaking of Italian Gothic, with which Sir Gilbert largely infused some of his later works, he observes the union of which it was the result "produced many noble and many incongruous developments." He also says truly it should be used with caution. We cannot follow the author through this most interesting lecture, which occupies a considerable portion of the first volume. The characteristics of the style, the various portions of buildings are minutely analysed, and some exquisite examples are engraved; the column and its base are traced, for example, through various changes, and the critical remarks on mouldings will be re-read with profit. The capitals given are unique types, while the western portals of St. Albans (p. 167) is a superb instance of this feature. The following lecture is devoted to some of the leading works of the thirteenth century, and here we find illustrations of the Temple Church, the movable reredos once belonging to the high altar at Westminster, containing very early painting ascribed to an Italian artist; details from St. Ethelreda, Holborn; east front of Ely; Peterborough Cathedral; the south-east portal of Lincoln, and various details of windows. A very instructive lecture is devoted to the "Rationale of Gothic Architecture," in which the author glances at various theories broached as to its origin. It is more to the point that in England the style was developed just when the great institutions of the nation were being formed, that no occult motive existed, but that common-sense applied to plain requirements became the sole motive. "A Digression concerning Windows" is the subject of a lecture in which the author enters into the rationale of splay and the two systems of arching the heads, called the *rere* arch and *through* arch, equally and so variously employed by the Mediæval architects. Lecture VIII., upon the Practical Study of Gothic, contains some very trenchant observations calculated to make many professing Gothicists feel somewhat ashamed of their ignorance of true principles. Sir Gilbert says "Gothic architecture is only to be learned from *old examples*," and the study should be continuous. Hints to students, and various examples in London and elsewhere follow; while in the next lecture the return to English types is strongly recommended, and one sensible suggestion made—namely, that in designing we should design *in English*, as good writers invariably write in their *own* language without recourse to foreign idioms. The advice, though it is less necessary at this moment, comes with much force from one who reached the highest pinnacle of success in the art by consistently following the principles of English Gothic, uninfluenced by the fashions and importations of his day.

In the second volume Sir Gilbert Scott reviews in greater detail the English developments of architecture, and from lecture X. the author commenced the course in his official capacity. In their practical interest to English students, these later discourses possess a new charm. They begin with the Celtic remains in Scotland and Ireland, and pro-

ceed with the churches founded by St. Augustine. Canterbury, York, and Ripon, the churches of Retham, Brixworth, Northamptonshire; Worth Church, Sussex; Bradford, Wilts; Castle Hill, Dover, churches at Monk Wearmouth and Stow, Sompting, Barton-on-Humber, &c., are among those described and illustrated, many in plan and details. The earlier Norman buildings, including Canterbury and Westminster, are considered, the characteristic features of the style are discussed, and the principles of treatment of doors, windows, arcades, and vaulting are shown to have been logically deduced from actual wants. In Lecture XII. the early architecture of Britain is continued, and examples are given of St. Albans, Winchester, Ely, Rochester, Norwich, Gloucester, Worcester, and Durham cathedrals, Tewkesbury Abbey, and Christchurch, Hants. The author thinks it was Durham that influenced Christchurch, not Christchurch Durham, as maintained by Mr. Ferrey. In the subsequent lectures the practical and artistic principles of Early British architecture are discussed, the conditions necessary to the arcuated style are distinguished, and the development of vaulting is thoroughly entered into. It is not necessary for us to comment here upon these lectures, as they have been given in the *BUILDING NEWS*, and fully illustrated. They comprisesome beautiful examples of vaulting, from the plain barrel vault of the Romans to the fan and traceried vaulting seen at Henry VII.'s Chapel. The dome, a favourite theme with Sir Gilbert, is the subject of another lecture (XVI.), in which the developed forms in France, Germany, and Italy are fully described. The pendentive dome is specially dwelt up as capable of being engrafted upon the Gothic, and the author welcomes the cupola, "the noblest of all architectural features," into our revived Gothic architecture. This fact is illustrated by the author's premiated design for the new Parliament House, Berlin (see p. 289), and for the Central Hall of his new Law Courts design—illustrations, however, that do not worthily exhibit the real merits of these designs. Allowing for the somewhat discursive manner unavoidable in the lecture form, we have no hesitation in saying Sir Gilbert Scott's work is one of the most complete and most philosophical expositions of Medieval Architecture that has yet been published.

ROYAL ACADEMY LECTURES ON ARCHITECTURE.

EARLY RENAISSANCE—BRUNELLESCHI.

IN his fourth lecture, Professor Barry dwelt upon the re-birth of Classical ideas in the Gothic architecture of Italy, as specially exemplified in the building of the Certosa and the duomo added to Arnolfo's cathedral at Florence. The Italians, unlike ourselves, broke at once and for ever with Mediaeval architecture, and to this day regard Gothic as barbarous. The Early Renaissance architecture might be studied according to two types. One of these was more affected by the work immediately previous to itself than was the other. The Certosa at Pavia might be regarded as an illustration of the one school, and the works of Brunelleschi as examples of the latter. In the former building they had a building of great richness, with varied details, many very beautiful, but with a complete absence of repose. The architects had borrowed features, without scruple, from the rival styles known to them. There were the beautiful arcaded galleries surrounding the upper part of the semicircular apses, familiar in Lombard churches, and rendered into Northern language in the early buildings of Cologne. Circular arches prevailed in the windows, but the pointed form was also represented. The turrets, with their spire-like tops, gave an effect of verticality, while the enriched cornices asserted the horizontal principle. The elaborate structure, half-tower, half-dome, which covered the intersection of nave and transepts, was one of the

few existing examples showing what might have been the treatment of the dome by the Italian architects of the Middle Ages. It was designed in accordance with the tradition of the day, altered by an admixture of details intended to be Classical. It was composed of successive stories of small columns and arches, gathered inwards, till the summit could be crowned by a small octagonal cupola. The general effect was fantastic, and could not be commended; but it was interesting, as illustrating an attempted compromise between the Mediaeval lantern-spire and the dome. Taken altogether, much could be said in favour of the Certosa, in an architectural sense. It was inconsistent, and its details were wanting in purity of style; nevertheless, many of its parts were admirable, such as the delicate arabesques in the pilasters of the chief façade, which exhibited a refinement of design and execution seldom surpassed. Scarcely any other single building illustrates more clearly the confusion of ideas which ushered in the Renaissance. The movement was one of vigorous individuality in details, without the controlling authority of a strict general design. The Early Renaissance was a period of experiments; of essays, rather than achievements. The designs of the period exhibited a life and elasticity which might have been turned to better account, and with the greater knowledge of the past possessed by modern architects, it might not be too much to hope, even yet, for a skilful adaptation of a style based upon the works of this first period of the Renaissance.

Turning from the Certosa to the Cathedral at Florence, a marked difference in character was observable, although the interval between the periods of erection was not great. The Certosa was commenced about 1396, and Arnolfo died at the commencement of the same century, leaving the arches of his great church unfinished, and his plans for finishing its dome, or domes, altogether uncertain. The completion fell to Brunelleschi, who finished the dome just before his death, which occurred in 1444. At this period the Certosa had been all but completed, with the exception of the western front, which was not commenced until 1473. After the death of Arnolfo long doubt and delay occurred, and at length the question of the day with Florentines was, "How to finish the Cathedral?" Arnolfo had provided enormous thicknesses of wall, to support a great weight of superstructure. He, doubtless, contemplated an inner dome at a lower level than the existing structure, and he may have thought of some aspiring design recalling, externally, the Gothic lantern and spire, as at the Certosa and at Chiaravalle, near Milan. If there existed any idea, however, of realising such a conception, it was abandoned altogether at the bidding of Brunelleschi. A Florentine by birth, Brunelleschi had early acquired the friendship of Donato, and with him visited Rome. This journey was the turning-point of Brunelleschi's career, and determined his subsequent taste in architecture. It is thus recorded that the Pantheon formed a part of his especial studies, and his subsequent proposals were probably based upon an admiration of the simple dome of that unique building. He made plans of temples, baths, palaces, theatres, the Colosseum, and other monuments of old Rome, from which he thought he could learn the methods of the ancients. He then returned to Florence, full of the conclusions he had formed, and as eager as any modern Revivalist to extol the merits of the half-forgotten architecture of the past. He found the authorities in the midst of divided counsels and heated discussions. Architects and engineers had been summoned from afar, and were in full debate as to how the work should proceed. Brunelleschi declared his opinion that the walls should be carried higher; that windows should be pierced in the upper parts of the walls of the octagon; and that the dome should be commenced at a much higher level than Arnolfo had intended. While making these suggestions, he kept back his explanation of the actual methods for carrying them into execution. They were consequently declared impracticable by rival competitors for popular favour, and appeared little likely to be approved. It was curious to note the alternative plans for filling up the central blank. The great question was the need of scaffolding, or internal supports, for so vast a dome, while in process of construction. To meet this difficulty it was proposed to fill up the space with earth, in which money should be imbedded

as the mound rose; and that, on the completion of the work, permission should be given to the people to fetch away the earth, and keep all the money they could find! Other proposals were made for the erection of a central column, or of several internal piers, with arches turned from them, to support a massive scaffolding above, on which the cupola might be raised. It was declared impossible to erect the latter of stone or other solid material, and cysteolite, or sponge stone, was suggested as an alternative. Brunelleschi listened to these proposals with ill-disguised impatience, and, at last, roundly declared that they were worthless, and that the dome could be built without such contrivances, and with no sacrifices of solidity of material or of architectural grandeur. He was voted a dreamer and a madman, and laughed at as a simpleton. In the end, however, the Florentines had to claim the assistance which they now despised. The question was referred to the syndics of the woolworkers and the wardens of the church, and in their difficulty they requested Brunelleschi to lay before them his detailed proposals. It then appeared that he had carefully considered the difficulties of the case, and had matured plans which he was ready to pledge himself to carry out. His written report to the syndics and wardens contained a full description of his ideas. He alluded to the large dimensions of the building, both in width and altitude: the diameter of the dome being 137ft., and the height 280ft.; and decided that the dome should be octagonal on plan, so as to snit the walls, and that the section should be pointed. By this design a certain harmony was secured between the plan of the church and the domed roof over it, but could not be regarded as having solved the problem of a Gothic dome. In the neighbouring baptistry there was an example of an Early Pointed dome of octagonal plan, which may well have served as Arnolfo's model in his general design of his far greater work. There was, therefore, no novelty in Brunelleschi's suggestions, beyond the scale of the work. His originality displayed itself in the proposal of great height, a departure not only from the intentions of Arnolfo, but also from architectural precedent in dome construction. By raising the drum beneath the dome, Brunelleschi evidently desired to obtain a grand external effect, as well as a noble completion of the interior. This had been the aim throughout of the Renaissance architects in contrast with that of their predecessors, who had made the dome the actual crown of their building as well as its ceiling. Brunelleschi's work was rather an octagonal roof, with curved sides, than a dome, in the strict sense of the word. He adopted the Northern method of double construction; but with so little difference between the inner and outer sections, that the whole may be considered a single design. He thus availed himself of the whole thickness of the double section where special strength was necessary, such as at the eight angle ribs. Between the angles he placed piers, two in each bay, to give stiffness to the filling-up of the compartments, and to serve as counterpoises to the thrust of the arch. Between the outer and inner cupolas was placed a circular ring or bond, formed of strong beams of oak, fastened together with iron. The circular bonds were used at about 18ft. apart, and the dome was carried up to a certain height in this manner, without scaffolding or internal support. In Brunelleschi's report he did not venture to premise completion of the work without scaffolding. He only undertook that it should be carried up to the height of about 60ft. From this point upwards he said it might be continued "after such manner as shall be determined on by the masters who may have to build it, since practice teaches us by what methods to proceed." For the lower part he advised the use of hard stone and marble, and for the superstructure, brick or sponge (spugne), for the sake of lightness. It is curious to mark the reserve which Brunelleschi exhibited in his suggestions. He seems to have pointed out the step to be taken at once, leaving his future intentions vague and undescribed. The Florentine authorities did not thoroughly trust him, for they associated with him Lorenzo Ghiberti, known to us for his famous gates to the Baptistry. Brunelleschi brooded over this mark of distrust, preparing his models in secret, and referring objectors to Ghiberti, as to difficulties which he felt sure his colleague could not solve. When the cupola was partially completed, he succeeded in getting left alone, and was appointed sole archi-

test of the fabric for life, with an annual allowance of one hundred florins. In order to facilitate the progress of the workmen he erected a scaffolding inside the dome, although there is no record of any centreing for the arch. On this scaffold he placed, amongst other things, wine-shops and eating-houses for the workmen, so that the latter should not lose time by descending for refreshment. At length, as Brunelleschi was approaching his seventieth year, the two cupolas were all but finished, and nothing remained but to add the lantern, above the circular space, or eye, at the top of the building. In accordance with his usual dilatory custom, Brunelleschi had left this matter unsettled, and while he was engaged on the models of this final detail, the end came. After his death the models were disregarded, and the present lantern was added by others. Brunelleschi died in 1446, at the age of sixty-nine, and was buried in the church to which he had devoted the best years of his life. He figures, therefore, worthily in the list of the Fathers of the Italian Renaissance. He found the Gothic styles of Italy in vogue, but to him the glories of old Rome were the guiding star of his architectural life, and when he died, his mantle fell on other great artists, who were henceforward to conduct the movement.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE fortnightly sessional meeting of the Institute was held on Monday evening, the President, Mr. C. Barry, in the chair. Mr. WURRE, secretary, announced the death of Mr. C. J. Adams, Fellow, of Stockton-on-Tees. Mr. T. H. WYATT, hon. secretary, notified to the members that M. Pascal Coste, of Marseilles, had just died, in his 92nd year. Mr. Wyatt added that he had received a letter from Herr Lepsius, of Berlin, one of their gold-medallists, pressing the Institute to elect Herr Gropius, the Government Architect, as an hon. and corresponding member, and forwarding photographs of works he had executed. The President said Herr Gropius would be nominated at the next meeting, and the Council felt justified in recommending his name, as he had conceived and carried into execution many important works, of which an architect might well be proud. The President then read an extract from a Freemasons' journal, with reference to the election of Bro. John Gibson as Grand Superintendent of Works for England, in succession to the late Bro. Frederick Pepys Cockerell, and said all members would congratulate their old friend and colleague, Mr. Gibson, on his appointment.

Mr. David Ross, of Dunedin, New Zealand, was elected as Fellow; and Mr. John Slater, B.A., of Bedford-row, W.C., as Associate.

GREEK ART AND GREEK GEOMETRY.

The President invited discussion on Mr. John Pennethorne's paper, "The Connection between Ancient Art and the Ancient Geometry, as Illustrated by the Works of the Age of Pericles," read at the previous meeting (see pp. 183, 212), remarking upon the extreme refinement which the author had shown to exist in Greek architecture, extending even to placing a building in the best point of view, and arranging every proportion to suit that view. That these calculations were successful, the admiration of all subsequent ages had testified.

A paper, written by Mr. F. C. PENROSE, was read for the author by Mr. Cates. The author expressed his admiration of the research, thought, and careful measurements displayed by Mr. Pennethorne, in his researches into the optical refinements of the Greeks, and his regret at having to dissent from some of his conclusions, more especially that as to the supposed corrections for certain definite points of view. He had carefully tested, from three given points of view, Mr. Pennethorne's scheme, for the proportion of a Greek temple in three instances. In one of them he found the supposed corrections very closely coincided with the actual measurements; but in the other two he did not obtain nearly so satisfactory a result as was given by Mr. Watkiss Lloyd's method of proportions—a theory which he thought both simple and more likely to have been adopted by the Greeks. These points were illustrated by a number of comparative detail measurements, which Mr. Cates drew out upon the black board.

Mr. WATKISS LLOYD thought it would be

almost a shame to demolish a system on which Mr. Pennethorne had bestowed so much thought, ingenuity, and labour. He was, however, of opinion that neither the ancient author he quoted from, nor the actual buildings, confirmed the whole of the author's conjectures. The passages in Vitruvius referred to appeared to relate to the mimetic arts, especially to sculpture. It was clear, however, from these passages that attention was paid to optical effects, and entases were given to columns, square openings in lofty situations were designed as parallelograms, and what were to appear as circular openings as ellipses. He did not believe that these refinements were yet further adjusted to suit some one special point of view. His own theory as to their principles of designing, based on study and measurement of the principal buildings, was that the architect had first to consider the general proportions of the apartments into which his structure would be divided, and that he aimed at making these symmetrical and proportionate. Then he distributed these elements in accordance with his taste, and so as to fall in with a canon of numerical proportions governing the general arrangements. In the Parthenon the numerical canon was based on a difference of 5 between the two members. Thus the upper step on the longer and shorter sides, bore a proportion of 4 to 9; the entire height of front to breadth of upper step was as 9 to 14; the height of columns and architrave to same step as 4 to 9; and the entire height of facade to same step as 2 to 7. The actual measurements bore out these proportions not exactly, but within very trifling variations. The height of the column agreed with the breadth of the front with a difference of 1, given in favour of the column, and this rule was borne out by all the chief Greek temples.

Mr. H. H. STATHAM protested against architects allowing themselves to be overridden with figures. By cutting up the parts of a building into such small parts, and omitting the "slight discrepancies," some numerical series might be found by which the wildest Gothic cathedral would be reduced to system. The new point in Mr. Pennethorne's paper was, that he supposed Greek architects designed their buildings to be inspected from some one point of view. Incidentally he must take exception to the argument that the charms of architecture, like those of music, could be reduced to no fixed rules, for harmony depended on the synchronous recurrence of certain vibrations, whereas in architecture there was no corresponding law. He noted that three separate bases of comparison were taken—the upper and middle steps, and the podium; all could not, he thought, be right. Then the point of sight had been assumed at 45°; if so the Greeks were wrong, for the most complete view was obtained at 33° from opposite the centre. Further, if all these minute adjustments were calculated to suit, say, the north-western approach, they would mar the appearance from the south-eastern point of view. The explanation offered was that the pavement at the east end was so much broader than at the west, that when viewed from its edge this was set right—a suggestion with which he could not agree.

Mr. CATES, on behalf of Mr. Pennethorne, replied on the discussion, referring to the attack made upon Mr. Pennethorne's theory by M. Lesueur, who had attributed the variations in the Parthenon to settlements due to imperfect foundations, and had declared that in no case did a long line of building appear to sink in the middle, nor were any other optical corrections needed. At Athens, said Mr. Cates, an instance of want of attention to these corrections might be seen in the Academy of Fine Arts, built by Messrs. Hanson, of Vienna, and Ziller, of Athens. Every detail was carefully executed in white Pentelic marble, and with a refinement only inferior to the Parthenon. Yet the effect of the whole is heavy, the columns seem to lean, the entablature sinks in the centre, and the whole is distorted, simply because no regard was paid to optical corrections. The angle of 45 degrees might be a mistaken point of view, but that was the fault of Greek architects; the fact that all the principal temples were approached from such an angle gave colour to the theory. Perhaps if similar attention were given to architecture as had been devoted to music, the harmony afforded by certain lines and proportions might be established as a law in design. The systems both of Messrs. Pennethorne and Lloyd seemed to agree with measurements of Greek buildings, if they eliminated from every calculation certain unimportant frac-

tions. But since it would be allowed that the Greeks made many refining corrections in their works, was it not reasonable to go a little further and admit the possibility that they made such minute—often, perhaps, empiric—adjustments, as to render the appearance of a building more harmonious from given points of view?

The President having closed the discussion, invited Mr. J. K. Colling to read his paper upon "Architectural Foliage," but Mr. Christian protested against commencing, at 9.45 p.m., a paper which would occupy at least an hour to deliver. The President suggested the desirability of carrying out the programme, but by a show of hands it was unanimously decided to adjourn the meeting. The President announced that the next meeting would be special, and for members only, and that the next ordinary meeting would be held on March 21st, when Sir James Watson would read a paper on "Improvements in Glasgow." An endeavour would be made to enable Mr. Colling to read his paper the same evening.

ARCHITECTURAL ASSOCIATION.

THE INTERNATIONAL CONGRESS OF ARCHITECTS AT PARIS.*

(Concluded from p. 197.)

THURSDAY was devoted to an excursion to Rheims, and on Friday the question of competitions was discussed, when the following resolutions were passed:—1st. "That the Minister of Public Works be requested to reorganise the system of public competitions throughout France, and to place them on a basis such as would give satisfaction to the interests of artists, the common welfare, and the requirements of State administration." 2nd. "That the basis should consist of a series of rules defining the drawing-up of a programme, and the nomination of a jury consisting of architects, instead of leaving the selection and judgement to the prefects and mayors." The lecturer said he suggested that, as this congress was an international one, it would not be asking too much that the resolutions should be modified, so that they would be applicable in other countries. He doubted whether the prefects and mayors of France would give up their powers and rights of selection, especially when it was the money of their own provincial towns which was about to be spent. He also laid before the meeting a copy of the Institute rules, in which the utmost demand was that an assessor (an architect by profession) should assist the municipal authorities. Senor Bohnars and Herr Klein, the delegates from Spain and Denmark, deplored the mismanagement of competitions in their respective countries. M. Strohman, the Russian delegate, contended that architects should be placed on the Committee of Adjudication, and that competitors ought to be allowed to appear before this committee, not only to explain their own designs, but to criticise those of other competitors. On Saturday, at a sectional meeting, a letter was read from the Commander da Silva, president of the Architectural Society of Lisbon, describing the cathedral at Batalha and its late restoration. This cathedral is especially interesting to us, as it is considered the architect must have been an Englishman, from its resemblance to some of our minsters. It was built towards the end of the 14th century by King John I. of Castille, who imported a large number of architects from all countries, so that a building should be constructed which should be without a rival. It has just been restored by the Chevalier Santos Periera. The concluding meeting of the Congress was held at the Trocadero in the afternoon. The chairman, M. Guillaume, member of the Institute of France, and Director of the Ecole des Beaux Arts, distributed the medals and prizes given by the Société Centrale des Architectes. The large number of prizes given by the Academy of France and the School of Fine Arts render it unnecessary that the Société Centrale should hold any further competitions or give prizes to students. It takes up, therefore, another field, that of rewards for executed works. It is now five years since these were instituted, and there seems to be no ill-feeling or jealousy created as to their justice of decision. There are two classes of prizes—those given to architects for the best specimens of domestic architecture erected within a certain number of years, and those to workmen employed in the

* A paper read by R. PHENE SPIERS, F.R.I.B.A., on February 14th, 1879.

building trade, and to manufacturers of special wares used by architects. To facilitate the distribution of the second class of awards, all the architects of Paris and the provinces are requested to report to a committee of the Société the names of any contractors or workmen who have executed work under their order worthy of special notice. These "contractors" are not the capitalists and speculators of our country, but the actual workers themselves, independent foremen of each trade. The committee's choice has to be approved of by the council of the Société. The principal rewards given this year were as follows:—M. Henri Blondel and Charles De la Lande, architects, of Paris, and M. Gosset, architect, of Rheims, were awarded medals for their executed designs for Domestic work; M. Henri Révoil, a medal, for a work on the Romanesque architecture of the south of France; M. Metz, architectural expert, a medal, for assistance rendered in the Courts of Justice; M. Homolle, the society's large bronze medal, for archaeological excavations in the island of Delos; to M. Dutheil, stonemason and "pie-quer" (setter-out of masonry), who passed a brilliant examination in stereotomy, a silver medal was awarded; and to M. Dumnain, stonemason, a bronze medal; the next medal was given to M. Delhomel, aged 73, who in 1829 entered the service of the contractors for the restorations at Amiens Cathedral, and for 45 years has been the foreman mason employed in setting the stonework of the cathedral, having been commended for his exactitude, intelligence, and his upright character by the various architects superintending the work; to M. Banet, described as "good builder," was awarded the next medal. It is recorded of him that when the great demolitions were commenced in Paris about 30 years ago he was employed in the work, being allowed to sell for his own benefit the materials pulled down, that being his reward for his trouble. Finding his benefits to be too great, after deducting what he thought was a fair remuneration for his services and risk, he offered the remainder to the municipality, who, finding that there was really a considerable profit in the undertaking, since that period have put up to auction the privilege of demolition. To his chief foreman was awarded a bronze medal. To M. Baudet, civil engineer and constructor of ironwork, who carried out the iron construction of the roof of the National Library and other public buildings, a silver medal; and to his pupil and chief foreman a bronze medal. To M. Meril, forger of wrought-iron work, a silver medal, and to his foreman one of bronze. To M. Bernard, working joiner of Lyons, a silver medal. To MM. Geneste and Herschen, civil engineers, manufacturers and patentees of ventilating and warming apparatus, silver medals, and to their foreman a bronze medal. Those who have visited the Palace of Versailles will remember the magnificence of the lead cresting which surmounts the chapel roof. This has recently been restored under the superintendence of the lecturer's former professor and principal, M. Questel, the architect of the Palace of Versailles, and to the chief plumber and his foreman were awarded a silver and bronze medal respectively. Two other medals, given to M. Parville and M. Leibnitz, the manufacturers of the glazed terra-cotta work used in the decoration of the loges in the centre of the Exhibition buildings, concluded the list of rewards. It must be remembered that it is the custom in France to entrust the different trades of a building to different specialists. This increases the labour and difficulties of the architect, but it has the counter advantage that the specialist contractor, who in many cases is still the actual worker on the building, has the subject at his fingers' ends; he takes a great interest in the work, and can execute it at much less cost than a large contractor, being content with a smaller profit. The last address at the congress was by M. Desjardins on the Campagna of Rome, and the proceedings terminated with a banquet at the Grand Hotel. As to the results of the Congress, Mr. Spiers said he did not think much practical benefit was effected. It would have been more useful if the preliminary arrangements had been more carefully thought out. Scarcely the titles of the papers were known before the meeting, and each reader commenced his discourse with an apology for what he called "the tyranny of the title." The chairmen and other officers were not chosen till the meetings commenced, and then half-an-hour was lost in the appointment. The

resolutions were not formulated in advance; in some cases were scarcely put in a definite form. No committees were appointed to continue the work, and one's only astonishment is, that so much was got through; so many excellent, if too theoretical, addresses delivered; and so much interest and sympathy awakened in these who took part in the proceedings.

Mr. RIDDETT, in proposing a vote of thanks to the lecturer, remarked that it was gratifying to learn that the conduct of public business was not one of the things which they did better in France. The relations and distinctions between the architect and the engineer appeared to have been fully discussed. It was clear that until the engineer became more artistic and the architect more scientific in their constructions there could be no usurpation of each other's provinces. Mr. Spiers had mentioned that clerks of works were unknown in France. The position of a clerk of works was anomalous; he was generally chosen from a class of men who had been all their lives in a builder's employ, and he feared architects did not always get what they wanted from him. He trusted the custom would grow of having in his stead a resident architect on the works, who would, at the same time, be gaining valuable experience for after practice. The French system of contracts was very different to ours. There were indeed no contracts, but the work in each trade was carried out by a separate workman at so much per cent. below the municipal schedule, and as the whole was measured up at the close, it was not to be wondered at that in the architect's scale of charges was a fee of six francs per hour for settling the differences which might arise. With the vote of thanks he would couple another to Mr. Spiers and their President for so ably representing the Association at the Congress.

Mr. CLARKSON seconded both votes of thanks. He did not entertain the fear that the architect's work was likely to pass into the hands of the engineer in this country, for the engineer's province was restricted to constructions of a utilitarian character. There was no doubt, however, that the very large amount of ecclesiastical work which had fallen to the architects during the past five-and-twenty years had been somewhat prejudicial to the profession; but there was now a tendency to require that young architects should divert their attention from the examination of old works to the study of modern problems of construction and design, and of contemporary buildings. The new Post-office buildings in St. Martin's-le-Grand had been incidentally alluded to as the work of a Government engineer. That was hardly correct, for the Mr. Williams, their architect, was one of the Fellows of the Institute, and a duly qualified member of the profession, although he had the misfortune to be in official employ in connection with the erection of Post-offices throughout the kingdom. The system of a uniform scale of percentages appeared to have been considered at the Congress as unfair, but this was not the case; the young architect who had but a small practice gave a larger amount of attention and thought to each building than the man at the head of his profession could afford. Architects of large practice ought, he thought, to weed their business and only take large and important works. As to diplomas, in England these were not half so much value to the public as to the profession; it would force men to go through a regular curriculum and would give them the power and mastery over their work which resulted from labour devoted to study.

The PRESIDENT, in putting to the meeting the vote of thanks to Mr. Spiers, intimated that the remarks of their representative were listened to with great interest and attention at the Congress. With all its defects, he believed the Congress would have a very good effect; the subjects were all practical and had a direct bearing on the profession. The mode of subdividing the contracts in France led to far more attention being paid to the work than prevailed in England, and the result was satisfactory although it entailed in supervision a vast amount of trouble upon the architect. Some modification of the two systems might perhaps be found practicable in this country. He then put to the meeting the vote of thanks, which was carried by acclamation, and responded to by Mr. Spiers, who further explained the workings of the Parisian schools of fine arts and design, and the French system of contracting.

COLOUR IN ARCHITECTURE.

A PAPER upon this subject was read before the Birmingham Architectural Association, on the 11th inst., by Mr. J. W. Tonks. Modern building, he remarked, was, before all things, utilitarian; but while the architect was expected in the first place to produce the greatest results at the least possible cost, there was also a desire for what was beautiful, and an emulation to obtain the most ornate or beautiful buildings, existing not only amongst municipalities, but amongst the owners and occupiers of dwelling-houses. The problem before the architect was how to produce satisfactory and pleasing structures without unduly increasing the cost, and this must be solved in one or all of three ways—by variation of the sky-line, by the recess or projection of portions, and the enrichment of surface. The play of contrast in the roof-line could be obtained in Gothic by pinnacle, parapet, cresting, and slope of roof; in Tudor and Elizabethan by an enlarged variety of expression and clustered chimneys; in Palladian by cupolas, pediments, and pavilions; and even in Queen Anne by hat-boxes of quaintest form and roof accretions. There were four styles in art. Some variety of sky-line could be introduced with advantage by the architect. The second mode of light and shade in architecture by recessing or projecting parts of the frontage, presented great difficulties in execution to town architects; no encroachment could be made upon a street front, and land was too valuable to be sacrificed in unnecessary recesses. The requirements of light also militated against this mode of treatment, but something might be done by means of column, cornice, parapet, and even verandah. As to the third requirement of *chiaroscuro*, little need be said of the enrichment of surface by moulding or carving. The tendency to decorate was usually sufficient to carry the designer to the full length of his client's purse. To be effective, ornament must be in its place, it must supply a want, and it must not obtrude itself unduly. The last method considered was the actual use of colour in external architecture. Iron, brick, wood, and stone all admitted of a certain amount of distinctive surface effect and colour. When the building was new, or in the case of wood and iron, when fresh paint had been applied, the result might be satisfactory, but the atmosphere of a manufacturing town would soon efface all expression, and all these materials faded under the influences of smoke and rain to uniform hues. The question arose whether coloured surfaces could be employed which would be impervious to both influences. The polished surfaces of granites and coloured marbles were but slightly affected by the atmosphere, and these materials afforded a basis of distinctive colour, but the use of these were necessarily restricted by their expense. Mosaics were a still more costly luxury, but will probably play a more important part in the future than they had done in the past. Mosaic was now being introduced into the decoration of a public building at Birmingham—in the central arch of the front of the Council-house. The use of terra-cotta of different colours was now common on the Continent, although but little adopted in this country. It was being used on a small scale and with good effect in the School Board offices and the Grand Hotel in Colmore-row, Birmingham. A little harshness of colour was pardonable when the material was being introduced, for it would speedily tone down, and an architect's impetuosity and foresight in designing and construction would add to his reputation in after years. Majolica ware and faience had been freely employed in the Pavillon de Ville de Paris at the recent Exhibition in that city, a building designed by M. Bordouard, and intended to become permanent as a gymnasium. It was composed of a framework of iron, clothed with bands of brickwork, terra-cotta, majolica tiles, or slabs. The age of frescoes for external decoration had, the author considered, gone by, although it would still be used in the interiors of important buildings; the begrimed, plague-stricken effect of an old fresco on a decaying wall was depressing. Painted pottery was in a different case; it would not lose colour, and a broken tile could be replaced; it did not retain dirt and could be easily cleansed, and any tint or tone could be obtained by its use. When or where to use it would require careful consideration by the architect.

SANITARY SCIENCE AT THE SOCIETY OF ARTS.

THE Council of the Society of Arts have formed a Sanitary Section, and have appointed the following gentlemen as a Committee in charge of it:—Mr. F. A. Abel, C.B., F.R.S.; Mr. R. Brudenell Carter; Mr. E. Chadwick, C.B.; Mr. Henry Cole, K.C.B.; Major-Gen. Cotton, F.R.S.; Captain Douglas Galton, C.B., F.R.S.; Mr. Coghlan McHardy; Mr. Robert Lawlinson, C.B.; Dr. B. W. Richardson, M.A., F.R.S. The Committee will meet periodically for the discussion of sanitary subjects. Communications of a suitable nature are invited. The annual Conference will be held in the rooms of the Society of Arts, on Thursday and Friday, the 15th and 16th May, 1879, on National Water Supply, Sewage, and Health, the Right Hon. James Stansfeld, M.P., late President of the Local Government Board, in the chair, assisted by the members of the Executive Committee.

PROGRAMME OF PROCEEDINGS.

The conference will meet each day at 11 a.m., and sit till 1.30, then adjourn till 2, and sit again till 5 p.m., and, if necessary, meet again at 8 p.m.

Thursday, 11 a.m.—Opening of the Proceedings by the Chairman.

Papers and Discussion.

Friday, 11 p.m.—Proceedings will be resumed. Papers and Discussions continued.

There will be an Exhibition of Mechanical and Chemical Apparatus in connection with Water Supply, Treatment of Sewage, and Health. All articles for exhibition must be delivered, carriage free, not later than Saturday, the 10th May, 1879. Manufacturers and others desiring to exhibit should communicate forthwith with the Secretary of the Society of Arts. Papers on any of above heads are requested. The object of the Conference is to discuss existing information in connection with the results of any systems already adopted in various localities, referring to the subjects of National Water Supply, Sewage, and Health; to elicit further information thereon; and gather and publish, for the benefit of the public generally, the experience gained. The introduction and discussion of untried schemes will, therefore, not be permitted. The papers accepted for the Conference will be printed and circulated at the meetings.

The Council have determined to offer the gold medal of the Society, and three silver medals, for the best suggestions, founded upon evidence already published, for dividing England and Wales into watershed districts, for the supply of pure water to the towns and villages in each district. The suggestions must be sent in to the Society's office on or before the 26th April, so as to be discussed at the Conference. The details of the conditions will be issued immediately, and may be had, when ready, on application to the Secretary of the Society.

HOUSEHOLD SANITARY ARRANGEMENTS.

ON Monday evening, at the Society of Arts, Dr. W. H. Corfield, M.A., delivered the second of a course of Cantor Lectures, on "Dwelling Houses: their Sanitary Construction and Arrangements," the subjects treated of this evening being "Ventilation, Warming, and Lighting." As on the previous occasion, the lecture was illustrated by various specimens and models from the Parkes Museum of Hygiene. Dr. Corfield commenced by an account of the way in which air is polluted by respiration, far more by the putrescible organic matter discharged into it than by the diminution of oxygen or the increase of carbonic acid. The amount of air necessary for each person per hour is 3,000 cubic feet, and as the air can only be changed three or four times an hour without draught, it follows that each person must have from 750 to 1,000 cubic feet of space; and this must be properly distributed, for it is evident that a man could not live in a space one foot square, and 1,000 feet high; any height above eleven feet should not be considered in estimating the air space of an ordinary room. Ventilation is divided into two kinds—natural and artificial. Natural ventilation means those methods which make use of the ordinary physical forces of nature which allow air to go in certain directions. Artificial ventilation means the forcing of air into buildings or drawing it out by steam-engines, water-

power, horse-power, &c. Ventilation by fires and lights forms a connecting-link between the artificial and natural methods. In order that air may be changed there must be openings for the pure to come in and for the vitiated air to go out. A considerable quantity of air goes out by a chimney whether there be a fire or not. It is of extreme importance to have windows on both sides of houses, so that the air may go straight through them. Sylvester's plan for the ventilation of large houses was by means of a cowl always facing the wind, on a pipe which carried air into a cellar where it was warmed by stoves, and then passed through apertures into the various rooms and out by an exit shaft. Dr. Richardson improved the cowl by utilising the aspirating power of the wind upon the same principle as the spray producers on scent-bottles. Air outside being colder, is heavier and exerts greater pressure than air inside a house. If a hole be bored in the wall of a room, air will come in as water would. Window sashes can be made to act as ventilators. Dr. Hinxes Bird's plan was to open the lower sash and fix in a well-fitting block of wood. This left an opening between the sashes in the middle of the window, and the air was admitted in an upward direction. One objection to this plan was that people seeing the window open complained of draught; another objection was that it did not purify the air. Another plan was to cut pieces out of or bore holes in the lower board of the upper sash, these holes might be filled with cotton-wool, and blacks would thus be kept out. Currall's lower-sash ventilator is a metal plate in front of the lower bar of the lower sash, admitting air in an upward direction. A model of an automatic fastener, invented by Messrs. Thompson and Sons, of Birmingham, was exhibited and explained. It allowed a window to be opened any distance at top or bottom, and always held it fastened. Louvre ventilators were next spoken of. If a window be pulled down a little at the top and a Venetian blind let down, with the louvres sloped upwards, that answers perfectly well. Moore's ventilators are glass louvres in a metal frame. They ought to be in the lower panes of the upper sash, but are generally fixed too high. Inlet openings ought not to be near the ceiling. Sashes may be made to fall in and form immense louvres; and such are in use at Willis's Rooms. Double windows are sometimes used to avoid having a cold stream of air near the window. French casement-windows are not suitable for this climate. If they be used some kind of louver ventilator is necessary. One of Cooper's ventilators may be used, being a circular disc of glass with five holes in it, and corresponding holes in the frame behind; the disc turning on an ivory pivot. Inlets through walls may be provided with a sloping board in front, having sides or cheeks. The inlets should only be just above a person's head. A metal box of this kind was shown, having a balanced metal flap, easily moved by a cord. Several small ventilators are better than one large one. A drawer ventilator was next exhibited, being a box to be fixed in the wall, having inside a drawer fitted with metal plates for giving an upward direction to the air. Perforated zinc is sometimes used with the idea of filtering the air; but it is better to have simply an iron grating which will keep out birds. Filtering may be effected by cotton wool, a spray of water, or some other means. A ventilating inlet in a door is sometimes useful, but conversation in the room can be heard outside. In Tobin's system of vertical tubes, a horizontal pipe, with a grating outside, comes through the outer wall into the room, where there is a vertical pipe about six feet high, from whence the air rises up in a column. Valves, or trays fitted with plates, and holding water to filter the air, may be added. A long raised muslin bag may be inserted, and this would separate a great deal of impurity from the air. Ellison's conical ventilators contain simply conical holes, which are placed with the small end outside and the large end inside the house, whereby, it is said, much less draught is occasioned. A conical siphon is also suggested. Of exit openings chimneys are most important. If they be not higher than surrounding buildings cowlings are sometimes necessary. Fixed cowls are generally better than movable ones, but were not always effectual. Dr. Arnott's exit valve consists of a light metal flap swinging on a hinge at its lower edge, and so weighted that it balances. It has two disadvantages: one being that it opens directly into the chimney flue; the

other that it makes a noise; but a valve was shown and worked which made a noise hardly perceptible. These valves might be very properly used in situations not leading into chimneys. Fire-clay flues are being made by Doulton, in which the chimney heats the air in two tubes and causes an up-draught from rooms connected with them. These flues are better with valves, especially where the flues are not always in use. Boyle's exit valve is an improvement upon Arnott's, and consists of a series of small tale flaps. Benham's plan is one for carrying off products of combustion of gas and vitiated air from the upper part of the room at the same time, but by different pipes, fresh air being brought in from another direction. A model and drawing of this arrangement were shown and explained. Verity's system of artificial ventilation, recently applied in the Reform Club, uses water from a cistern as the moving power. The water from a pipe strikes against a wheel, and turns a ventilating-fan at a considerable rate, by means of which air could be forced into a room or drawn from it, passing along a tube, in which, if used as an inlet, ice, or a disinfectant or deodorant might be placed. For want of time, the subjects of lighting and heating will be considered at the commencement of the next lecture, when the subject of water supply will be taken up.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—At the meeting last week, Mr. Thomas Morgan, F.S.A., in the chair, further discoveries connected with the Roman villa at Ichen Abbas, a small Norman church, once belonging to St. Mary's Abbey, at Winchester, were communicated by Mr. E. Loftus Brock, F.S.A. The villa, which was small, must have been one of great beauty, and faced the south-west. The plan of the portion of the excavations already made shows it to be about 50ft. by 15ft., with an extension to the east. In this small square there is a passage, approached by what has been apparently an arch of some elegance, since the basis of stone columns remain. There are four apartments connected with this passage, three of which are paved with tessellated floorings of good design, the one in the third room being very fine, with a centre figure representing Flora. The colours of the tesserae are well-preserved. A large quantity of wall plaster has been found, the greater portion nicely ornamented, with the colours as fresh almost as when first applied. The fourth apartment has not yet been excavated, but trial shafts have not revealed pavement of any kind, so it is probable it never was so ornamented. No more coins have been discovered, though plenty of pieces of pottery of various kinds, and mostly indicating vessels of very beautiful forms, are constantly met with. Workmen lately employed in making drains for the sewage of Winchester have come upon a portion of a very elegant Roman pavement, of which the colours are very bright and well-preserved, and this pavement, with the above remains at Ichen Abbas, the many still existing at Winchester (*Venta Belgarum*), the pavement at Bramdean, and the extensive remains in Lord Northbrook's plantation near Micheldever, sufficiently prove how widely and thoroughly settled were the Romans in and near the valley of the Itchen. A paper was read by Mr. George Patrick upon "Burghley House," illustrated by a series of old drawings. The chairman announced that the Council had resolved to undertake some further explorations at Castor, commenced 50 years ago by Mr. Artis, whose valuable work on its pavements, altars, and other interesting Roman remains is so well known, and solicited the aid of the Association and the public generally, by way of a private subscription, for carrying out so desirable a work.

Messrs. Wm. Furness and Co., of Liverpool, have introduced a most convenient and economical glue heater, heated by means of steam. The glue-pots, which are of copper, fit into a cast-iron casing divided by partitions, so that any or all of them can be used as desired. The large oval pot will take a cake of glue without breaking, and is used to supply the smaller ones. The pots are surrounded by water, in which the steam blows, over-flow pipes being provided. A steam pipe runs along the front of casting with separate cock into each compartment. There is also a pet cock for drawing hot water to make the glue the right consistency.

ST. MARY'S R.C. CHURCH, BATH.—ST. BARNABAS' CHURCH, BECKENHAM.—ART UNION OF LONDON NEW PREMISES.—NEW WAREHOUSE AT BELFAST.—PORCH AT LINCOLN CATHEDRAL.—A WAYSIDE INN.

OUR LITHOGRAPHIC ILLUSTRATIONS.

SOUTH PORCH, LINCOLN CATHEDRAL.

The porch on the south side of the choir, known as the Presbytery entrance, is a beautiful, and in England rare, if not unique, example of the porches so common in France, and though inferior to the best of them in size and richness of decoration, is altogether an excellent example of the period. The chief object of interest is the doorway, the sides and arch-mouldings of which are very much enriched with rows of figures and strings of foliage alternately; presenting every variety of surface to the fleeting light and ever-changing shade, and showing gradations of colour quite impossible to do justice to in a pen-and-ink drawing. The alto-relievo over the doors embodies the idea of the last judgment (as described in the 25th chapter of St. Matthew's Gospel), and was evidently executed by a sculptor not unacquainted with the excellences of ancient art. The arrangement of the subject is very praiseworthy, from the importance given to the central figure, the Supreme Judge of Man, by its size and situation, in which circumstance it possesses almost a peculiar merit, since the great masters, both in sculpture and painting who have treated the subject, have usually made the Divinity secondary to the display of character in the objects of hope and despair. Mention is made of this alto-relievo in Flaxman's lecture on composition, and an illustration of it appears in his work. The four statues in the piers of the porch are the four Evangelists, and were no doubt the work of the same hand, as the superior portions of the rest of the work. It is probable that a statue of the Virgin and Child was placed on the middle pier, as at the entrance to Lichfield Cathedral, which is of the same age and style. The chapels at the sides of the entrance, which are very nearly alike, though by no means adding to the beauty of the early work, are nevertheless good examples of the Perpendicular style. That on the east side is the chapel of St. Blaise, built by Bishop Russell, who died in 1494, and on the west is the chapel of St. Catharine, built by Bishop Longland, who died in the early part of the 16th century.—W. H. W.

ST. MARY'S CATHOLIC CHURCH, BATH.

This new church is being built for the Very Rev. Canon Loughman, from the designs of Messrs. Dunn and Hanson, of Newcastle-upon-Tyne, to replace an old one known as the "Upper Chapel," in Montpellier, Bath, which was formed some years ago out of stables belonging to the riding-school, into a temporary church. The new building is situated in the Julian-road, about three hundred yards distant from the old one. In plan, the church consists of a nave 76ft. by 22ft., and with a south aisle has a total width of 36ft. 6in., a sanctuary 33ft. 6in. by 22ft., side chapel 27ft. by 13ft., and sacristies 39ft. long, with sacristan's-room and organ-chamber above, the latter opening upon side of

sanctuary with an arcade of four arches. The whole is being built, inside and out, of Bath stone, with the exception of red Mansfield columns in the nave, and red granite in the sanctuary. The clerestory runs at same height along both sides of the church, and below it, on the north wall, are stone panels, to be filled with paintings. The roofs are all of dressed pitch-pine, that of the sanctuary being groined up to a large moulded purlin, over the clerestory of five windows. The central portion is a pointed barrel vault divided into panels with carved bosses at the intersections of the mouldings. The contract is being carried out by Mr. Joseph Bladwell, builder, of Bath.

ART UNION OF LONDON NEW PREMISES.

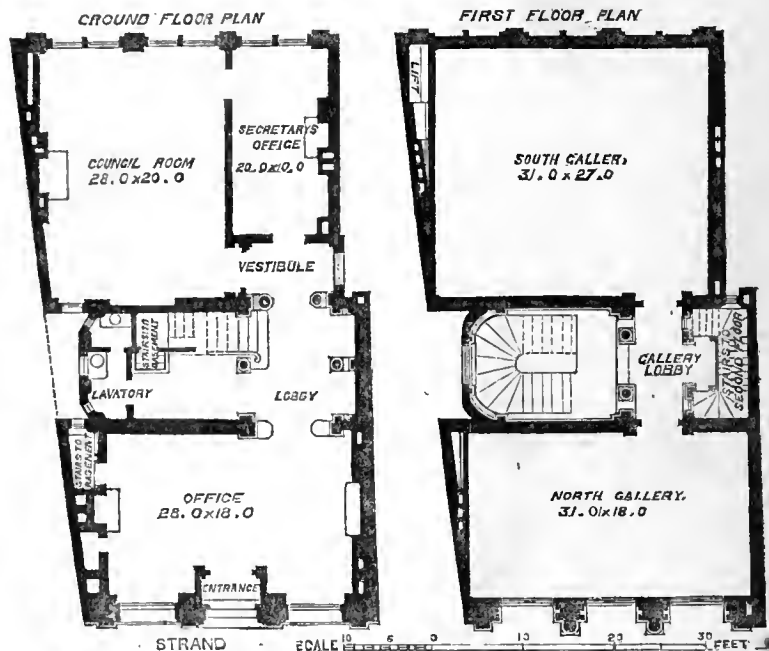

THE Art Union of London, instituted in 1837, has found its operations successful to such an extent as to require enlarged arrangements for the transaction of its increasing business. Having set aside a fund for the purpose of acquiring suitable premises, the Council lately decided to invest the same in the erection of a new building in the Strand, on the Savoy Estate. They decided that the architecture should be Palladian in style, and intrusted the work to Mr. Edward

ST. BARNABAS' CHURCH, BECKENHAM.

WE give this week another illustration of St. Barnabas Church, Beckenham, Kent, to be erected in a portion of the parish, to which a new district has been assigned. The site is on rising ground, a short distance from the main road from Beckenham to Bromley. The foundation for the chancel have been put in, and a memoria stone, which will be immediately under the altar was laid by Earl Nelson on June 11th, 1878, a President of the Free and Open Church Association. The church will be constructed of Kentish rag stone for the external walls, with Godstone freestone for internal ashlar; the wall between the Kentish rag and freestone being filled in with concrete. Red Dumfries stone will be used for the shafts, bands, &c. The chancel will be groined. The church will seat about 1,000 persons. All the seats to be free, and the estimated cost £18,000. Messrs. Alex. R. Stenning and Henry Hall, of 27, Fenchurch-street, are the architects, the work being personally superintended by Mr. Alex. R. Stenning.

WAREHOUSE IN DONEGALL-PLACE, BELFAST.

THIS building has been erected in place of one destroyed by fire about two years ago, for Messrs.

M. Barry, R.A. The new building contains, on the ground floor, a front office or shop, and at the back, a council-room and a room for the secretary, looking over the ground attached to the Savoy Chapel. The first floor is occupied by two galleries for the exhibition of pictures and sculpture. The front gallery, towards the Strand, is lighted by the three arched windows of the principal story. The other, and larger gallery at the back, has a top light only. The basement is occupied by carpenters' workshops, packing-rooms, and stove-rooms, and there is also a sub-basement, which was rendered necessary by the great depth of the foundations. The building rests upon a continuous bed of concrete, about 3ft. thick. The front is of Portland stone throughout. The principal story is marked by the employment of a Corinthian order of columns and pilasters, with arched windows deeply recessed. The spandrels over the windows, and the pilasters, are carved with subjects suggestive of the practice and influence of the fine arts of painting, sculpture, and architecture. The device of the Art Union, used on seals and official documents, is carved in low relief on a circular shield in the tympanum of the pediment over the doorway. The site has presented some irregularities and difficulties with respect to light and air, which have affected the arrangement of the plan. The contractors are Messrs. Perry, of Tredegar Works, Bow, who expect to finish the building before midsummer next. The sculpture has been executed by Messrs. Mabey, of Prince's-mews, Westminster. Mr. House is the clerk of works.

Lindsay Bros., wholesale warehousemen, Belfast. The building contains nearly an acre of floor space. The top floor is to be used for cooking, dining-rooms, &c., for the employees of the firm, and the remainder of the building for warehouse purposes. The enrichments of the front are of terra-cotta, from Messrs. Johnson and Co., Keymer Junction, Sussex. The builder is Mr. Robert Corry, Belfast; the clerk of the works Mr. Jas. Moore; and the architect Mr. Robert Watt, of Belfast.

A WAYSIDE INN.

A fortnight since we published the design placed first in the competition for a wayside inn, and to-day we present our readers with the drawing, by "Meehlin," whose design obtained the position of second in order of merit. This position, as we have already said, is chiefly due to the appropriate architectural treatment employed, though the plan has also points of merit.

The owners of St. George's Church, High-street, Borough, were last week, at the Southwark Police-court, summoned by the Metropolitan Board of Works for an order to take down or otherwise secure the head of the south-west door and the west front of that edifice, and to secure the brick and stone work of the front or flank walls. Evidence was produced proving that the portions of the church mentioned were in a cracked and otherwise insecure condition, and that no attention was paid to notices intimating the dangerous state of the structure, which were served at the church by the district surveyor. Mr. Partridge made an order for the necessary repairs to be carried out in six weeks.

RESIDENTIAL BUILDINGS IN VICTORIA STREET.

ONE of the most important visits by the Architectural Association was made last Saturday afternoon to two blocks of residential flats in Victoria-street. One of these, called the "Alexandra Mansions," we have already illustrated in the BUILDING NEWS of January 10. We here, however, more particularly describe the block called the "Members' Buildings" as the most complete of the two. It occupies a wedge-shaped plot between Victoria-street and another street; the corner portion, however, at the junction, has been set apart for banking premises. We may observe that the architect, Mr. Francis Butler, has adopted what may be called the "staircase" in contradistinction to the "corridor" system of arrangement. There are two main entrances, and these lead to spacious halls common to the various sets of residences. Three staircases give access to the several sets or suites of apartments, and each of these have two landings; in fact, the principle of the system is to give each set of apartments its own landing, and thus obviate the frequently-urged objection of making one staircase serve as a communication to several sets of dwellings. The number of rooms to each residence varies; in some cases there are four and five rooms, and in others three and five, each suite having its own landing and entrance. Each set comprises an entrance and hall, tenants' and porters' lifts, a w.c., a sitting-room (in some cases double with folding-doors) and two or more bedrooms. The kitchen and stove occupy the basement, and the whole of the service is under the control of the manager. The smaller suites of rooms are let, we are informed, at £150 per annum, and the larger at £200, and these sums include attendance and taxes. The cooking may be contracted for between the tenant and the manager, and the system has all the advantages of the co-operative plan. The floors are fire-proof, and the sanitary arrangements are pronounced perfect. In the "Alexandra Mansions" four residences are obtained on each floor approached by two staircases. The principal rooms vary from 20 feet by 17 feet to 14 feet by 12 feet. In each residence there will be a hall, with lift and w.c., and a corridor approach to a principal room, sitting-room, bedroom, and dressing-rooms, besides kitchen, scullery, and offices. Light is derived from a central area.

Architecturally, the former design is marked by some ingenuity in the planning. The staircases in both buildings are made important features of the interior. The newels are of stone, the stairs of veined marble, and the entrances and landings are paved with encaustic tiles. The stone arcades in the lobbies and landings relieve the generally cold look of these approaches, and the form of arch and the details are in a domestic French-Gothic—a sort of Transition between Florid Gothic and Renaissance. The lighting of some of the passages and rooms appeared to us insufficient, though, to do the architect justice, he has shown some skill in the lighting areas in cutting off the angles of projections. In so cramped a site, and in a building of such a height, lighting was a matter of difficulty. The entrances to the members' buildings, with thin, flat, elliptical doorheads, having vine-and-oak foliage carved round the jambs, are made conspicuous features, together with the bays. The centre doorway leads by a wide corridor to an elongated octagon hall, with lantern over 20ft. by 15ft., placed obliquely to the axis, and from this hall access is obtained to two sets of residences in front, and to a corridor in the rear. On the right side is a suite of rooms with its own entrance hall, two front sitting-rooms, about 16ft. by 15ft., and two bedrooms. The bay projections add much to the spaciousness of the principal rooms; externally they form pronounced features, being carried up eight stories, including the ground floor, and two stories above the eaves level. A bold coved carved cornice marks this junction, while the chimney shafts assist to break the skyline. The termination of the bays is pleasingly managed and their pointed roofs also help to break the steep roof. There is a strong touch of French in these and other parts. The flat windows are also slightly projected, and form vertical features in the façade. Bands moulded and carved with panels of varying form and design, connect the parts horizontally, while between the ground and first stories a balcony, boldly corbelled out round the bays and richly charged

with carved panels, forms a conspicuous feature. The whole of the façades are executed in Tisbury stone ashlar, supplied by Mr. Alford, and present a very imposing appearance to the street. We may note that the windows are mullioned with transoms, the angles and heads being rounded at the corners. In the Alexandra Mansions, illustrated by us, a similar treatment of the façades is noticed, but these are still unfinished. We observe one improvement in the latter block—namely, the windows have balconettes. The corner also has an octagon bay or turret. It will be unnecessary here to describe the arrangement, the plans of which we have already given, but the same principle of planning has been followed out in the suites of rooms and *maisonnettes* on each floor.

INDIAN POTTERY.

MR. GEORGE BIRDWOOD, on Wednesday evening, read a paper at the rooms of the Society of Arts upon the subject of "Indian Pottery at the Paris Exhibition." He desired to draw popular attention to the interest awakened among the cognoscenti and curiosos of Paris in Indian pottery, and to the warning which he had elsewhere raised against the influences which were enfeebling and corrupting its artistic character, and which would only become aggravated by the commercial demand now sure to spring up for it, unless they were from the first intelligently resisted alike by its purchasers, importers, and manufacturers. After referring to pottery of English manufacture, he passed on to a description of the principal varieties of Indian pottery suitable for exportation, particularly mentioning the red earthenware pottery of Travancore and Hyderabad, the red glazed pottery of Dinapore, the black and silvered pottery of Azimghur and Surat, the painted pottery of Kotah, the gilt pottery of Amroha, the glazed and unglazed pierced pottery of Madura, and the glazed pottery of Scinde and the Punjab. In all these varieties of Indian fancy pottery an artistic effect was sought to be produced; but only the pottery made at Azimghur, and in Scinde and the Punjab, and the Bombay School of Art pottery, were exhibited at Paris, and it was only of these examples that he proposed to speak. In the best Indian pottery was also found the reverent subjection of colour and ornamentation to form, and it was in attaining to this result that the Indian potter has shown the true artistic feeling and skill of all Indian art manufacturers in his handiwork. The great secret of his mastery was the almost intuitive habit of the natives of India of representing natural objects in decoration in a strictly conventional manner; symmetrically and without shadows. In this way, the outline of the form ornamented was never broken. The decoration was kept in subordination to the form also by the monotonous repetition of the design applied to it, or by the simple alternation of two, or at the most three, designs. Also, never more than two or three colours were used, and, when three colours were used, as a rule, two of them were only lighter and darker tints of the same colour. The potters' art was of the highest antiquity in India, and the unglazed water vessels made in every Hindu village were still thrown from the wheel in the same antique forms represented on the ancient Buddhist sculptures and paintings. Some of this primitive pottery was identical in character with the vases found in the tombs of Etruria, dating from about B.C. 1000. The glazed pottery of Scinde was made principally at Hala, and that of the Punjab at Lahore, Mooltan, Jang, Delhi, and elsewhere. It was said that the invasion and conquest of China by Chingiz Khan, in 1212, was the event that made known to the rest of Asia and Europe the art of glazing earthenware; but, in fact, the Saracens from the first used glazed tiles for covering walls and roofs and pavements, and of course with a view to decorative effect. Mr. Birdwood, after describing the technical details of the manufacture of Indian pottery, and referring to the habits of the Hindoo villagers, in conclusion said that he had gone fully into the Indian patterns, surroundings, and antecedents because they could only proceed profitably in their inquiries by the chronological and historical reduction of the origin of art. It need not be enforced, he thought, how much an intelligent study of economical and historical influences under which the arts of India had been produced and were sustained, would help

to a fuller understanding of the origin and development of the Indo-European art generally. In the course of a brief discussion, in which Mr. Andrew Cassels, and Mr. Kipling (of the Government School of Art at Lahore), Mr. Doulton, and others, took part, it was stated that all articles of Indian manufacture had of late appeared to indicate a decadence of Indian art.

COMPETITIONS.

BRISTOL UNIVERSITY COLLEGE.—The Council of Bristol University College met last week to consider the plans sent in by eight architects for the new building, and they decided on appointing Mr. Charles Hansom, F.R.I.B.A., as their architect. On Thursday, Friday, and Saturday the plans were exhibited to the public. In addition to Mr. Hansom's design there were designs furnished by Messrs. Stuart Colman, J. H. Hirst, F.R.I.B.A., John C. Moncrieff, Lysaght and Scoones, E. H. Edwards, S. C. Frupp, and H. Crisp. Mr. Hansom's design is in the Tudor style. Mr. Stuart Colman sent in two pen-and-ink bird's-eye views. Mr. E. H. Edwards furnished a design for a two-story building, which would occupy about 80 feet in depth of the site and run parallel to the wall inclosing the property of the Blind Asylum, leaving an average depth of 96 feet, on which hereafter to erect the north wing and new front. An alternative design for a three-story building occupies a similar position to that proposed for the two-story structure though it is more compact in plan. The approximate estimates were between £8,000 and £9,000. A perspective in pen-and-ink, by Mr. John C. Moncrieff, was submitted, the style being Early Gothic. Mr. Henry Crisp's elevations were evidently considered as subservient to the plans, and treated simply as sketches, thus literally answering the request of the council in their instructions to architects. Mr. Frupp's design shows an elevation in the modern Italian style. The plan does not provide for any ornamental building to be erected hereafter in front of those now required, but it gives all the accommodation set forth by the council for the college and the chemical department with abundance of light and air, at an estimated cost of about £7,300. The estimates sent in by the different architects varied from about £8,000 to £18,000, Mr. Hansom's design costing about £15,000, which, judging from the accommodation at present required by the University, about 200,000 cubic feet, exclusive of passages, store-rooms, attics, foundations, &c., is not extravagant. His scheme, when completed, will cost between £25,000 and £30,000.

BUSHEY.—We have seen the five sets of design submitted in competition for the erection of a new church at Bushey, Herts, to cost £5,000, with tower, giving space for eight bells, and to accommodate 500 people. Mr. W. Young, of Exeter Hall, sends a pen-and-ink perspective, showing the tower above the choir, but excludes the cost thereof from his estimate. Messrs. Pillan and Page, of 18, Buckingham-street, submit a coloured perspective and interior, with tower over north porch; estimate, with tower, £6,500. Mr. R. Raikes sends a coloured perspective, showing tower and spire at north-west entrance. The chancel is apsidal, and the exterior treatment differs from that of the rest of the designs, which are of the usual type. The upper stages of tower and spire are not included in the estimate. Mr. W. H. Syme, of Watford, has a coloured drawing, and also a perspective in pen-and-ink. Tower is shown over south transept, and there is a strong resemblance generally to the Baptist chapel recently erected by the architect at Watford. Mr. Syme backs his estimate by a builder's tender guaranteeing the execution of the work for £5,200. Messrs. Coe and Robinson send two coloured perspectives, one showing the proposed church in red brick, and the other in Wolverton stone; tower and spire over north-western entrance. There is also a highly-coloured interior, the elaborate fittings shown in which are probably not meant to be included in the estimate. The design is the best of the five; Mr. Young's, in our opinion, coming next. Two of the other competitors find it necessary to find accommodation for part of the congregation in transepts, which are uncalled-for in a church of the kind proposed.

TAUNTON.—The proprietors of the North Town Nursery Estate, Taunton, recently invited plans for laying out their property as building sites, offering a premium of £50 for the best plan, and

£10 for the second. Over a hundred sets of plans were sent in by architects and surveyors in all parts of the country, from Burrow, Lowestoft, Falkirk, Dublin, and Edinburgh, &c. The owners were assisted in their adjudication by Mr. Davis, a local builder, and made the following awards:—1st premium, Messrs. Habershon and Fawcner, of Bloomsbury-square, London, W.C., and Newport, Mon.; and Messrs. Poole and Jones, Wandsworth-common, London, S.W.; placed next in order of merit, Messrs. Medland and Son, Gloucester, and Messrs. Erril and Clive, Chesham. Messrs. Habershon and Fawcner's plan has been adopted. It is conceived on purely utilitarian principles, the aim being to get as many houses as possible upon the given area, so as to produce diversity of class and amount of general rental; 135 plots of various sizes are shown.

BOOKS RECEIVED.

Brian Boru, a tragedy, by J. T. B. (London: Longmans, Green & Co.) is, as we have already announced, the work of a member of the architectural profession, whose name is well known to us and our readers, and some of whose buildings have been illustrated in our own pages. We have little space to spare for notices of purely literary works, but we feel sure that everyone who buys a copy of the book will be charmed with it. It is so simple and natural as to remind one frequently of the greatest of dramatists, one of whose well-known plays it somewhat resembles in plot and character, without, however, any suspicion of plagiarism. "J. T. B." will, unless we are much mistaken, be remembered as the author of "Brian Boru" long after the most substantial of his buildings has crumbled into ruins.—*The Patenters' Manual*, by James and J. H. Johnson (London: Longmans & Co.), is the fourth edition of a guide which has stood many an inventor in good stead, and will prove invaluable to many more.—*Luxton's Price Book for 1879* (London: Kelly & Co.) appears for the sixty-second time, and, as usual, leaves little to be said about it, except in commendation of the care exercised in its revision and preparation.—*Spon's Architects', Builders', and Contractors' Pocket Book* (London: E. & F. N. Spon) is another work of a similar kind, and equally excellent.—*Our Domestic Poisons*, by Henry Carr, M.I.C.E. (London: W. Ridgway), is a noteworthy account of the poisonous effects of certain dyes and colours used in domestic fabrics.—*The Fight with Infection*, by W. Stephenson, M.D., F.R.C.S.E. (Aberdeen: D. Wylie & Son), is a cheap and handy treatise, giving much valuable information respecting infectious diseases, which all should possess, which many have felt the want of when required, and which medical men have not always the ability or time to impart.—*Useful Information on Practical Electric Lighting*, by Killingworth Hedges, C.E. (London: E. & F. N. Spon), may probably be of service to people unacquainted with the subject, but contains little likely to be new to electricians.—*The Steam-Engine of the Future*, by John Bourne, C.E. (London: John Bourne & Co., 66, Mark-lane, E.C.), is a shilling treatise which should be read by every steam user in the kingdom. There are but few of them, we imagine, to whom the name of its veteran author is unknown.—*The Ornamental Penman's Alphabet* (London: E. & F. N. Spon) may be useful to engravers, stonecutters, and others, although there is nothing very new or ornamental about the few styles of letters not to be found in all other copy-books of a similar kind.—*Fuel: its Combustion and Economy*, edited by D. Kinnear Clark, C.E. (London: Lockwood and Co.), is a new edition of one of the well-known volumes of "Weale's Series." The very large amount of new matter added really renders the book practically a new one, and few engineers are better qualified as exponents of the results of recent progress in the economy of fuel than the gentleman to whom the work has been entrusted.

PARLIAMENTARY NOTES:

BACK-TO-BACK HOUSES.—Sir S. Waterlow last week asked the President of the Local Government Board whether that Board had, after communicating with the local authorities, conceded the principle of erecting back-to-back houses; and, whether he would object to lay upon the table of the House a report upon the subject prepared by Mr. Netten Radcliffe, of the Medical Department of the Board, and Mr. P. Gordon Smith, the Board's architect,

after local inquiry in the districts where the concession of the principle was granted. Mr. Selater-Booth—It would not be correct to say that the principle of erecting back-to-back houses has been conceded by the Local Government Board, but it is true that in the case of Idle in the North Brierly Union the Board have stated that, owing to the exceptional circumstances of the locality, they considered that this form of construction might be recognised, provided certain conditions could be complied with, and the regulation brought within the operation of by-laws under the Public Health Act. But no by-laws have as yet been submitted by the local authority, so that none have as yet been sanctioned by the Board. I should mention that one of the peculiar circumstances is that Parliament has sanctioned back-to-back houses in the neighbouring towns of Leeds and Bradford. There is no objection to lay upon the table of the House the reports of Mr. Netten Radcliffe and Mr. Gordon Smith on this case.

METROPOLITAN FIRE BRIGADE.—In answer to Mr. Ritchie, Mr. Cross said he was unable to say whether the Government would be able to introduce this session a measure dealing with the subjects reported on by the Select Committee on the Metropolitan Fire Brigade. It was, no doubt, a very important subject, and one to which the attention of the Government had been called by a recent occurrence.

WATER SUPPLY OF LANCASHIRE AND YORKSHIRE.—On Tuesday, Mr. S. Howard, seconded by Mr. Wheelhouse, moved for a Royal Commission to inquire into the deficiencies of the water supply of Lancashire and Yorkshire, and into the necessity and expediency of resorting to the lakes of Cumberland and Westmoreland. In support of it he canvassed the evidence given before Committee on the Thirlmere scheme last year, contending that it had not adequately considered the question from the public point of view. Mr. Selater-Booth was of opinion that the grounds assigned by Mr. Howard were entirely insufficient to justify the appointment of a Royal Commission, and pointed out that there already existed ample information on the subject in various Blue-books. Mr. W. E. Forster and Mr. Raikes advised the withdrawal of the motion; and Dr. Playfair, the Chairman of last year's Committee, vindicated the completeness of its inquiry. The motion was then withdrawn.

Building Intelligence.

INCORPORATED CHURCH BUILDING SOCIETY.—The Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels held its usual monthly meeting last week, at 7, Whitehall. The following grants were voted from the general fund, viz.:—Towards building a new church at Jump, in the Parish of Wombwell, near Barnsley, York, £150; building the new church of St. Paul, Lozells, in the parish of St. Silas, Birmingham, £200; rebuilding (on a new site) the church at Duddo, near Norham-on-Tweed, £80; and towards enlarging or otherwise improving the accommodation in the churches at Ashby-de-la-Zouch, £100; Backford, near Chester, £25; Black Notley, near Braintree, Essex, £25; Chastleton, near Moreton-in-Marsh, £15; Norwich, St. Augustine, £25; and Stanway, near Colchester, £50. Under urgent circumstances, the grant formerly made towards building the church of St. Lawrence, Morecombe, was increased from £300 to £350. Grants were also made from the Mission Buildings Fund towards building mission churches at Lead-street, in the parish of St. Matthew's, Leicester, £75; and Sturton, in the parish of Stow, near Lincoln, £50.

SOUTH SHIELDS.—The new Corporation stables at South Shields were opened last week. The stables are 90 feet by 30 feet, and have standing room for twenty-six horses, and two large boxes. Howorth's patent revolving foul air extractors have been used. The buildings were designed by Mr. Matthew Hall, Borough Surveyor, assisted by Mr. R. Greaves, and Mr. C. Cobham has discharged the duties of clerk of the works. The contract has been carried out by Messrs. D. Kennedy and Son, of Jarrow, at £4,000.

The renovation of Tuckingsmill church has now been completed. The chancel has been thoroughly restored by Mr. May, of Pool, from designs by Mr. J. P. St. Aubyn, and the cost has been about £320.

The Risca and Mynyddislwyn School Board have approved of plans prepared by Mr. Watkins, architect, of Newport, Mon., for a new school for 300 children to be built at Crosskeys.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the **EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.** Cheques and Post-office Orders to be made payable to **J. PASSMORE EDWARDS.**

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—B. and Co.—C. and H.—T.H.R.—E. and Co. T. S. Co.—W. and J. F.—McN. R. and Co.—B. B. Co.—F. W. B.—D. and H.—W. L. B.—B of S.—S. E. Co.—H. L. B.—G. and C.

L. W. (In reply to your queries as to hollow walls: (1) the quoins and dressings should not run through, but a cavity preserved all round. This is one reason why we prefer the greater thickness to be on the outside. If the stones pass the cavity, the damp is sure to permeate. (2) Most certainly the cavity should be carried round the chimney. The method you show in sketch is quite wrong, though many architects, in ignorance of the effects, adopt it.)—T. H. MENEITH. (All openings are deducted, except flues. If the rule you understood were adopted, most windows would be measured as solid. Order Treatise on Measuring published by Crosby Lockwood and Co.)

OUR COMMONPLACE COLUMN.—Notes or quotations upon the subjects of Glass Painting, Glazing, Gopura, Gothic, Granary, Orange, Granite, Greenhouse, Groin, Grotesque, Grouting, Gymnasium, &c., will be received on or before March 12th.

YOUNGSTER (Send to B. T. Batsford, 52, High Holborn, W.C., for a catalogue).

"BUILDING NEWS" DESIGNING CLUB.

As the following were unintentionally omitted in our review last week, we now mention them:—**OOMORE.**—(Pulpit weak in design: the base is squat, and the details lack knowledge. The figure in central panel would have been better omitted. We intended to place this design with others at end of article.)—**CHE SARA SARA.** (The last remark applies to this. The faults of the design are: the weak angle shafts: the shaft supporting book-rests and the mouldings have too many quirks.)—**RUSTICS.** (The defects of plan are the doors opening into living rooms, ill-lighted stairs, and no washhouse. Elevations are better. The design we intended to place in the last group.)—**RESEDA.** (We see your object.)

Correspondence.

PICTURESQUE ARCHITECTURE.

To the Editor of the BUILDING NEWS.

SIR,—I was pleased to see the letter in your issue of the 7th inst., from "An Architectural Fogey," and I heartily wish that the subject he touches upon could be ventilated thoroughly, with the effect of clearing and purifying the architectural atmosphere.

Of course, the idea of criticising any work of a master like Mr. Shaw may seem bold to many of us; but if an acknowledged clever designer, as Mr. Shaw undoubtedly is, is being so far led by, or is leading, the strange mania for it can

hardly be called by any other name) of the present time, so much the more reason for some one to protest, seeing the immense harm that will be done; for, of course, such a man always has shoals of smaller fry anxious to follow in his wake.

In the name of common-sense some one must protest against the vagaries of those whose sole endeavour seems to be to produce picturesqueness and quaintness at the expense of all true architectural feeling and consistency.

Though architecture is not to be expressed by the following of a set of arbitrary rules, yet laws of some sort must govern all true art; how the Church of St. Michael, on the Belford Estate, breaks through all rules, and only aims at picturesqueness, is so well put by your correspondent, that I need say nothing on that particular design. My object in writing is to raise another protest against the wave of "fashion" (most sad that even architecture should be the slave of fashion), which seems almost irresistible, but is likely to render the architect who falls under its sway, and proves it by his executed works, ridiculous to all but his mere contemporaries who are infected by the same mania.

We do not seem in a state of honest transition or development, but as a drowning man catches at a straw, so we are continually catching at some phase of art (?), and we copy Japanese, Queen Anne, Jacobean, &c., &c., in turn, anything, in fact, by the copying of which we can hope to produce something picturesque or quaint in feeling, either in building or decorating. Truly, there is no lack of "art" among us, but it is the art of copying.

THE BUILDING NEWS has always advocated truthfulness and fitness, as well as utility and beauty in architecture, and I hope that now, when such men as Mr. Shaw seem to be throwing aside all "old-fashioned" ideas of this sort in their determined (and, it must be confessed, often clever) efforts after mere picturesqueness, you will raise your powerful voice on the side of truth and consistency.—I am, &c.,

TRUTH IN ART.

MATLOCK CHAPEL COMPETITION.

SIR,—Your readers will, of course, see that the letter in your last paper from "Dixon and Moxon" in no way deals with the question. Let these gentlemen make no mistake. I congratulate them heartily on their good fortune in having such friends on the Committee; it matters not to them whether these friends are of sound principles or otherwise. But I do emphatically protest against being invited to compete, when all the time careful arrangements are being made which render the thing a farce, if not something worse. Nobody would have objected to the above gentlemen being appointed straight off.

"Dixon and Moxon" are right in one particular. The Committee are entire strangers to me, so, in case of success, I certainly should have considered that fairness, or at least impartiality, had been exercised.

I will not say more as to the superior unsuccessful designs, except that, as everybody knows, it is no difficult matter in a very short time to pick out a number of good designs from a large collection, but it would probably take much time to select one as the best.—I am, &c.,

"ONE OF THE UNSUCCESSFUL 83."

ARTISTIC BLOWERS TO OPEN FIRE-PLACES.

SIR,—The letter of "An Old Tee Square" on this subject reminds me that about six years ago we did the self and same thing he approves as "Mr. Burges' practical idea," with the exception of omitting the iron bar, which makes an unsightly line across the fire opening.

I found that if the plate-glass was properly bedded at the ends *loosely* it did not crack, and we also ground the bottom edge, which is an improvement.

One fire with a large square opening, all tile-jams and square dog-grate, puffed back smoke considerably; so we made a piece of plate-glass dip in the centre, like the old-fashioned buck-board of ladies' schools, grinding the bottom edge as before, and it was cured.—I am, &c.,

Fe. 24, 1878.

EDWARD STARR.

THE R.S.A. EXHIBITION.

SIR,—Brief criticism must needs be defective, but for any inaccuracy in the description of his design, Mr. Aitken is himself to blame. Had he read with understanding, he might have seen that the expression "inevitable tower and spire" was used generically, as descriptive of a number of designs besides his own; domical and pyramidal spires included. The expression was employed to note the singular fact, much more important than any detail of his design, that every church of any size, nowadays, is not considered presentable without a tower and spire. "Tower" and "spire" were used conjunctively to note another singular fact, that no tower, pure and simple, is enough, but it must have some superstructure, which cannot well be otherwise described than as a spire. Even in this Exhibition there are at least three varieties of the stunted spire. Mr. Aitken's was included, because it is not only an attenuated dome, but it has a turret on the top of it, and has thus a much greater affinity with the popular notion of a spire than with the idea of a dome; and in the general landscape of Dundee, distance, with its enchanter's wand, will unquestionably transform its rather ungainly curvature into the appearance of one of the numberless varieties of stunted spires.

The mistake as to the interior arrangement of the design was unavoidable, as there was no plan, and the description given very naturally credited the interior with the natural, economical, and artistic divisions indicated by the drawing. The perspective shows a nave and transept roof, also a nave and transept gable.

R. S. ACADEMY.

R.S.A. EXHIBITION.

SIR,—In your review of the architectural drawings, reference is made to the "exaggerated" scale of the design for New Church, Portobello. The drawing shows, by a joint in the paper on the face of it, that its size must have been an afterthought, consequent on the addition of a spire, drawn on an overlapping slip down the centre of the original.

The review, in another part, refers to a drawing being "preposterously large for its importance," and "placed close to the spectator." Yet there is a printed notice on the walls of this exhibition to the effect that its accommodation is limited.

Is it not possible that the hanging committee considered that there was something in the drawings which not only neutralised the effect of their size and scale, but entitle them to their position?

Another generalisation in the review calls for this comment: that in arranging the pictures on the walls of an exhibition it is usually supposed that the smaller and inferior pictures are used for "packing," not the larger.—I am, &c.,

JAMES FAIRLEY, A.R.I.B.A.

ARMY AND NAVY CLUB-HOUSE.

SIR,—In your notice of the reopening of the above in last week's BUILDING NEWS, you state that the "general repairs and renewal of furniture were entrusted to Messrs. Holland and Son." This, so far as the furniture is concerned, is perfectly true; but as the whole of the very extensive structural alterations and general repairs, as well as the entire decoration of the club, was carried out by us, under direction of H. R. Gough, Esq., the architect, we trust you will allow us to make this statement. As the decorations, in particular, have been very highly spoken of, we think it only fair that we should have our share of the credit.—We are, &c.,

THOS. WONTNER SMITH & SON.

79, Essex-road, Islington, N., 26 February, 1879.

"GAS IN THE HOUSE."

SIR,—I find your issue of Feb. 21 affords a full and fair criticism of my pamphlet under above title. Will you, however, permit me to point out two small errors affecting the sense of suggestions I have made:—In place of saying "no gas-pipe under 5ft. should be of less bore than $\frac{1}{2}$ in." I proposed that, "except for short distances (under 5ft.) no gas-pipe should be less than $\frac{1}{2}$ in. bore." Again, I have not advocated "gas-pipes and stoves" for bedroom use. It was to the merit of "gas fires" I desired to draw attention.—I am, &c.,

H. FARADAY.

3, Berners-street, London, W., Feb. 25, 1879.

CHURCH BELLS.

SIR,—In the current issue the Rev. R. S. Philpott inquires at what period church bells were first hung to wheels, and raised and rung in peals?

I have the authority of the Rev. H. T. Ellacombe, of St. George's Clist, the venerable and well-known authority upon campanology, for saying that in the very earliest fabric rolls and churchwardens' accounts items are charged for under the description of *bell-wheels*. But a whole wheel was not used before 1600. On the Continent they are seldom applied.—I am, &c.,

Exeter, Feb. 25, 1879.

HARRY HEMS.

Intercommunication.

QUESTIONS.

[5694].—**A Young Architect's Library.**—Will any correspondent compile a list of works showing how a young architect may, for a moderate sum—say, £50—get together such a nucleus for a library as shall not leave him without information on any practical subject he may have occasion to refer to in the course of his practice? Such a library should contain—1st, Geometry, drawing, and surveying; 2nd, Construction, with well illustrated details of the ordinary arrangements in all trades; 3rd, the principles and practice of ornament; 4th, scholarly works with details on the various styles.—THULE.

[5695].—**Measuring Plaster Work.**—In measuring up plasterers' work, are the openings of doors and windows deducted, and if so, would small windows be deducted such as 3ft. by 3ft. = 1 yard super? Are walls to be measured from floor to ceiling, or top of skirting-ground to under cornice?—A PIERCEWORK PLASTERER.

[5696].—**Brick Wall.**—Can any of your readers advise me how to construct a brick wall 16in. in thickness, having a cavity of 12in. in breadth? The bricks being 9in. long, I wish to know how the two portions of the wall, one 9in. thick and the other 4in., ought to be tied together.—C. C. C.

[5697].—**Weight of Wrought Iron Girders.**—In the articles on Quantities (Smith and Founder, 1st Vol., 1873) is an example for calculating weight of wrought girders, with dimensions, and states the same at 12cwt. 1qr. 25lb., but to be worked out by the reader. Independent of the rivets I make the weight 16cwt. 3qr. 4lb. The item for rivets I do not quite understand—viz., the 6, but which I think into the number of rivets 60. Will Mr. B. Fletcher kindly explain? I notice also queries by Wm. W., on p. 744, which I think remain unanswered.—LEARNER.

[5698].—**Royal Engineers.**—Will some kind reader give me a little information about the office of the Royal Engineers? I mean the office in which such drawings and works as Mayo College, illustrated in the BUILDING NEWS last week, are executed? How do you enter the office? Is it by competition? Is there any limit to age? And what knowledge do you require most, engineering or architecture?—D. M.

REPLIES.

[5649].—**Country Publichouses.**—"J. W. W." is no doubt in search of the picturesque in roadside publichouses. We know of no work upon the subject, and the old coaching scenes invariably picture imaginary inns. The half-timbered houses are far older than the coaching days, and the inns on the great roads contemporary with those days are of the plainest order. Here and there in the old towns of the Midlands, inns or publichouses are still to be seen of half-timber construction, and some of them possess a little architectural character. Taking Nottingham as a centre, the following may be noted in the town:—"The Postern Gate" where there is a remarkably fine wood ceiling; the "Cross Keys," in Brayard-lane, is a good type of an old tavern; the "King John's Palace," Widemouth-gate, a very quaint building, especially in the rear. Until late years, this town possessed an inn on the Long-row, called the "Old Bear." It was two stories high, with an attic in the roof, which consisted of sundry gables towards the front; and the ground-floor front was set back some nine or ten feet, and the superstructure was supported on wooden columns, a piazza being thus formed underneath. There are a few business shops on the Long-row of Elizabethan type that are very suggestive of ancient inns. In Grantham there are several half-timbered taverns of ordinary character, and there may be seen the celebrated inn the "Old Angel," which, by the bye, is of stone. Adjoining this inn is a fine half-timbered building, the first floor of which has a wooden balcony stretching across its front, a balcony that is protected by the overhanging story above. In Newark there are two old inns, the "Queen's Head," and the "White Hart." The former stands at the north-west corner of the Market-place, and the latter at the south-east, this is very ancient. We make this note as we are not quite certain of the names or signs of these inns. There are several blocks of old property in this town that are very picturesque and very suggestive of ancient taverns. In Mansfield there is the "White Hart Inn" in the Market-place; but modern improvements have stamped out its old character, save in the back elevation of the part over the gateway, where the original windows are left. In this part the original winding staircase exists, constructed of solid blocks of oak. In Worksop may be seen the "Ship Inn," a real old gem. Nothing is known of this house in the way of history, but its name suggests that it was so called in honour of Admiral Drake and his victories. This house is engraved in White's "Sheerwood Forest and the Ostleries," where it is said to have been in some part modernised. In Sheffield there are no old inns or taverns of this character, but there is an old building in the neighbourhood of the Midland station, adjoining the entrance of Mr. Longley's timber yard, a building formerly a lodge or farm on the estate of the Dukes of Norfolk. It is highly ornate, and is rich in architectural character; of late years it has sunk to the rank of cottage property, and it is hidden in part by neighbouring houses; nevertheless, there is sufficient material to enable its restoration to be easily made on paper. There is also some old property on "Sniig-hill" in this town that affords a little character in the upper stories. Outside the radius imposed by J. W. W., there is a remarkable building in Kirk-gate, Wakefield, called "Six Chimney House," and some very quaint old houses on the south side of Westgate, which, of late years, have been partly built up in front, and the overhanging character of the upper stories destroyed. The oldest half-timbered inns the writer is acquainted with are the "King's Head," a house suggestive of "Bluff Hal," in High-street, Hull; it is a house noted by old Taylor, the water poet. In the same street another old building exists, with a gateway in the centre; this is known as the "entrance to George-yard," and is said to have formerly been an inn. To anyone interested in the study of old property, the finest field to visit is the City of York, where

a month may be well spent by any artist. The most picturesque spots are the old shambles, the yards leading from the pavements, and in the old college buildings and their precincts.—W. S.

[5632.]—**Casts of Carving.**—"T. B.'s" remark that I am incorrect in saying pipe-clay is procured near Chudleigh, and his correction that it is found in the neighbourhood of Newton Abbot, is a trifle censorious. A glance at the map of Devon shows at once that Chudleigh and Newton Abbot are two little towns in the southern part of that county, some five miles away from each other, whilst the parish of King's Teigniton, the district where the major part of the clay is procured, lies somewhat to the east between the two. Hence my assertion and "T. B.'s" correction amounts to precisely the same thing. Besides pipe-clay, a deal of fine pottery's clay is also procured at King's Teigniton, and some two hundred men are kept constantly employed in the pits. They raise and send out on an average 50,000 tons per annum. The clay lies in beds varying from 20 to 80 feet deep. Pipe-clay is supposed to be decomposed granite, deposited by the hand of nature in the valleys where it is found. The clay varies in quality, and that should be selected for modelling purposes which is the most free from grit, and able to take a good polish, besides being tough and plastic in a damp state, though not too brittle when dry. The principal clay-workers at King's Teigniton are Messrs. Watts, Blake, Bearne and Co., who have business offices at Newton Abbot, Cornwood, and St. Austel. Messrs. Whiteway and Co. are also large clay merchants, and there are one or two minor firms besides, but the company I have first named do by far the largest business. It is Messrs. Watts, Blake, Bearne and Co.'s clay that is principally used at the various schools of art in this and other countries, and their pipe-clay is sent continually to every part of the civilised world. The cost of the clay wholesale is a guinea a ton, a tally of 70 "balls" going to the ton. Carriage to London is 5s. a ton by water (per Teignmouth), or about £1 for that weight by rail. Of course, when in a retail way the student pays a shilling for "a ball," he pays at the rate of £3 10s. a ton, so that to those who model a deal, and to all other large consumers, a considerable saving is effected by providing the clay direct from Devonshire. King's Teigniton is a village numbering 1,000 souls.—HARRY HEMS.

[5674.]—**Ordnance Datum.**—Thanks to "A. L." I should have done as he mentions, if the Ordnance Maps of my neighbourhood were published on the 6-inch scale, but there are none available at present. The one-inch scale maps do not give the heights of the bench-marks. There is an Ordnance work published "On the principal lines of Spirit-levelling in England," or some such title. Can anyone inform me if it gives the data I require?—BETA.

[5685.]—**Water-colour Drawings.**—My reply last week, under the head "Body Colour," will, I think, meet partly the query of "Y. Z." Mr. Ruskin is an admirable critic upon many things, but his recommendation as to body colour must be taken with reserve. I should certainly recommend "Y. Z." to follow the practice of "transparent colouring" in water-colours, as one less open to the trickeries of the art, and, moreover, the most natural way of laying on colour in this vehicle. Why should you mix, for instance, white with brown, to produce a lighter tint, if the same effect can be obtained by a simple wash of brown? If mere thickness of colour is the object, surely the process is not legitimate water-colour. But I may refer to some of our leading artists of the water-colour school, to show that the practice is avoided.—G. H. G.

[5686.]—**Bells.**—The method of calculating the number of changes on various bells is by multiplying the last remainder by the next number of bells. Thus, for two bells two changes, for 3, multiply 3 × 2, making 6 changes, for four bells 6 × 4 = 24 changes, for 5 bells, 24 × 5 = 120, and for 6 bells, 120 × 6 = 720 changes, and so on, up to any number.—D. H.

[5686.]—**Bells.**—The way in which to calculate the number of changes that can be rung on various peals is by beginning at number one bell, and multiplying by each successive number, continuing to do so until you get to the required number of bells, and the result will be the answer. Thus, the number of changes that can be rung on 4 bells is the following: 1 × 2 × 3 × 4 = 24 changes; on 5 bells, 1 × 2 × 3 × 4 × 5 = 120 changes; on 6 bells, 1 × 2 × 3 × 4 × 5 × 6 = 720 changes and so on.—M. JOHNSON.

[5686.]—**Bells.**—I should advise you to procure Benson's or Kort's book on change ringing. Benson's is the best; it will cost about a half-crown. That will show the best method for calculating the number of changes that can be rung on different peals; but four bells is scarcely enough to ring changes on: there should never be less than five or six.—W. S. TUPPITT, St. Columb Major.

[5686.]—**Bells.**—The number of changes that can be rung on various bells is found by multiplying the number of bells together, so taking the number of bells as per question, 4, we have 1 × 2 × 3 × 4 = 24 changes. The number of changes that can be rung with a number of bells less than the whole peal, is found by taking that number from the highest number downwards. Thus, required the number of changes that can be rung with 4 bells out of 8, 8 × 7 × 6 × 5 = 1680 changes.—H. VICTOR.

[5686.]—**Bells.**—The changes that can be rung on 4 bells are 24. Ex 1 × 2 × 3 × 4 = 24. Then 24 × 5 × 6 = 720. Then 720 × 7 × 8 = 40,320.—G. B.

[5690.]—**Gutters.**—I should have thought no one had any doubt respecting the superiority of iron over wood gutters. As regards suitability, perhaps the old wood lead-lined gutter is most in character with the Queen Anne style of building; it has also a substantial appearance, and can be modelled at a less cost than one of equal size in iron. As regards cost, iron, properly painted, is cheaper than wood because more durable. The special advantages of iron gutters are unquestionable: (1) it can be modelled to suit any requirement; (2) its channel is better shaped for water conveyance.—G. H. G.

[5692.]—**Girders.**—In reply to "Student" the simplest and best way to consider the calculation of timber girders will be, perhaps, to work from the strength of the material as known. A piece of red pine of in. square and 1ft. between supports is usually considered to break with about 4cwt. placed on its centre between supports,

and the following three rules or laws of strength always apply, and can easily be proved (if not of themselves obvious without) as being based on elementary mechanical laws. Law 1st. The strength varies directly as the breadth. Law 2nd. The strength varies inversely as the length. Law 3rd. The strength varies as the square of the depth. Now follows the question with respect to the factor of safety or constant, as it is sometimes called, when adapted to a particular material under some special conditions. One fourth of the estimated breaking strength is considered to be sufficient for safety under a fixed load, and one-sixth, one-seventh, or one-eighth as a factor of safety for a moving load, according to possible velocity. Let us consider the load mentioned by "Student," as the fixed load—viz., 20ft., bearing 14in. depth and 8ft. apart, and weight 1½cwt. per foot superficial of floor space. We have then 20 × 8 × 1½ = 240cwt., but half will, when equally distributed, be carried by the supports, which give $\frac{240}{2} =$

140cwt. bearing on the centre of the girder. Let us obtain the factor of safety by considering that the piece of red pine, 1in. × 1in. and 1ft. long, will support a safe load of 1wt. placed on its centre between bearings, then (if lateral twisting be prevented) a piece 1in. wide, 14in. deep, and 1ft. long, will support a safe load of 190cwt. and a piece 1in. wide and 14in. deep, and 20ft. long, will support a safe load of 196 ÷ 20 = 9.8cwt. We have 140cwt. to support, ∴ 140 ÷ 9.8 = 14.28in. wide. If I had adopted the factor of safety—viz., 7, quoted by "Student," the breadth would then have become 24.99—say, 25in., and in such case if instead of considering the load to be equally distributed and fixed we were to consider it to be on the centre and moving, the 25in. would then become 50in. being then nearly the same as the result by Tredgold's formula, and which frequently might be required in engineering works, and when it would become necessary to have them perhaps 1-3rd of that breadth and 2ft. 8in. apart, centre to centre. The preceding will, perhaps, render apparent the following formula, and which is consequent on the preceding laws and method adopted.

$W = \frac{c \cdot b^2 \cdot d^3}{l}$ where W = the safe load—(viz., the breaking weight of the material, divided by the factor of safety, which in our case was 4), b = breadth in inches, d = depth in inches, l = length in feet.—HENRY ARMROSE.

[5692.]—**Girders.**—"Student" has worked the rule on p. 65 of Tredgold correctly, except that he has taken W to represent a central load instead of a distributed one, which would reduce the breadth in the ratio of 5 to 8, or $\frac{5}{8}$ of 50.285 = 31.428 inches. This would be the breadth required for a girder 20 feet long by 14 inches deep, to support a distributed dead load of 31,360 lb. without deflecting more than 1-40th of an inch per foot. It is not, however, the proper rule for the girders of a framed floor, which are stiffened by the other timbers of the floor. "Student" will find the rule he requires on p. 126, art. 197 of Tredgold, edition of 1875, and also a table worked out by the rule on p. 457. Tredgold's rules for floor girders are calculated to sustain only about 1 cwt. per foot super, exclusive of the weight of the floor itself. If "Student's" load is 1½ cwt., including the floor, he must increase the breadth given by the rule on p. 126, in proportion to the increased load. "Student" should study the articles on floors, in Tredgold, p. 121 to 144. As to the transposition of the formula in Hurst's Handbook, its simplest form is $b = \frac{W \cdot L}{C \cdot d^2}$

If a factor for safety of 7 be taken for a live load, and allowance made for inferior timber, "Student's" example will work out to about 33 inches for the breadth, which is not too much to sustain a moving load of 14 tons, when the beam is not stiffened, as in a framed floor. It is evident from the results obtained above that for so long a span, and so great a load, as in the example given by "Student," an iron girder would be the most suitable.—J. S.

[5693.]—**Turned Newels.**—Turned newels are quite in keeping with "Queen Anne" work, but they should be massive. Hand-wrought newels are more pleasing. Of course, the top and bottom of newel should be square, or those portions against which the handrail and string stop. (See BUILDING NEWS "Joinery Details," lately given.)—G. H. G.

STAINED GLASS.

MANNINGHAM.—A stained-glass window has just been placed in the chapel of the Tradesmen's Home, Manningham, as a memorial to the late Henry Brown, J.P., of Bradford. It is the last of a series of thirteen executed by Messrs. Camm Brothers, of Birmingham. Mr. Brown was a liberal donor to the institution, and was its first chairman; his widow also built at her own expense the newly-erected almshouses. The window contains six subjects from Matt. xxv., and is illustrative of the acts of mercy; the two centre subjects are larger than the others, and executed in rich although well-toned colours; the upper and lower lights are treated in grisaille and gold, with a richly coloured and highly ornamented border.

MEMORIAL TO DEAN MANSEL AT ST. PAUL'S.—A stained-glass window has been erected in the north-west chapel of St. Paul's Cathedral, nearly under the west tower, to the memory of the late Dean Mansel, and it was uncovered on the Feast of the Conversion of St. Paul. The subject chosen for illustration is the "Incredulity of St. Thomas," as related in St. John xx. 24; and the work has been carried out by Messrs. John Hardman and Co., of Birmingham and King William-street, Charing-cross, under the direction of Mr. Penrose, architect to the dean and chapter.

ST. NEOT'S, HUNTS.—Two stained-glass windows have just been placed in the parish church of St. Neot's, at the expense of Mr. C. P. Rowley.

That in the north aisle represents the Healing of the Infirm Man at the Pool of Bethesda, John v., 2—9. In the centre lights are the figures of Jesus and the man who had the infirmity 38 years. The window in the south aisle is the subject of the Woman of Samaria, John iv., 5—28. The windows have been carried out in the richest style of the 15th century. They were exhibited in the Paris Exhibition by the executors, Messrs. John Hardman and Co., of Birmingham.

WATER SUPPLY AND SANITARY MATTERS.

BEDDINGTON SEWAGE FARM, CROYDON.—The Local Board of Croydon have decided to call in Mr. Bailey Denton, to advise them generally on the sewage arrangements of this farm, as well as on the advisability of deep draining the land, and the establishment of filter beds for downward filtration, so as to relieve the farm, and to make it more profitable.

DRONFIELD.—The works for supplying with water Dronfield and the other towns and villages in the northern division of the Chesterfield rural sanitary area are being carried out by Mr. Stevenson, of Eckington, the contractor, under the supervision of the engineer of the scheme, Mr. Frith, C.E. The site of the reservoirs is on the moors a short distance from Owlbar; they will be supplied from the Barr Brook. The estimated cost of works was £25,000, but it is expected that, owing to the reduced prices of iron and labour, the actual sum expended will be considerably less. The Rural Authority propose to give the inhabitants a constant supply of not less than 12 gallons per head per day, and that the cost will be less than 2d. per household per week.

HARWICH.—A Local Government Board inquiry was held at the Town Hall, Harwich, on Tuesday week, before Col. Cox, in reference to an application by the Corporation for sanction to borrow the sums of £10,000 for sewerage purposes, and £1,200 for the purchase of a site at Dovercourt for a small-pox hospital. The plans submitted under the sewerage scheme were those of Messrs. Ross and Mimms, of Westminster. They provide that the whole of the sewage shall be discharged into the sea at the breakwater from a pumping station on War Office land by means of a high and a low level sewer—the latter being Harwich, and the former Lower Dovercourt. The worst gradient was one of 1 in 892 for a short distance. The inspector said the board were committed to the opinion that it was necessary to proceed with the sewerage.

WATER FROM THE LOWER GREENSAND.—The lower greensand at Caterham has just been reached at the depth of 851ft. from the surface, and a supply of pure water is now flowing from it, and will shortly be used in the district supplied by the Caterham Spring Water Company. The boring operations were commenced on the 29th of July last with a boring of 18in. diameter, and the lower greensand was reached this week with a diameter of 15in., solid cores of the strata passed through having been obtained. Other borings are being put down by the New River Company at Turnford and Ware to prove the lower green sand at those places, while the Lambeth Water Company is putting down a borehole at Ditton to test the depth of the chalk basin at that place. The boring at Caterham has been carried out by the Diamond Rock Boring Company, who successfully reached the lower greensand at Meux's Brewery, Tottenham-court-road, in 1877.

The Local Government Board have informed the Lambeth guardians that they consider that the erection of an infirmary would be sufficient alteration at the industrial pauper schools at Norwood. The guardians have instructed their clerk to communicate with Messrs. Coe and Robinson, who were successful in the recent competition for reconstruction plans, and to draw their attention to the difference between their estimate of cost and that of the Local Government Board.

All Saints parish church, Hopton-by-Thetford, Suffolk, in the diocese of Ely, is about to be restored from the designs of Messrs. Satchell and Edwards, of London. For the execution of the work the tender of Mr. Brooke has been accepted. The restoration of St. Margaret's parish church, Wattisfield, in the same county and diocese, has also been intrusted to the care of Messrs. Satchell and Edwards.

A report by Mr. Douglas, A.K.C., respecting the progress of the new Eddystone Lighthouse, of which he has charge, states that since the works were commenced last July the weather had permitted only 135 hours to be worked on the rock although every opportunity had been taken advantage of. It is not expected that the work will be above high-water level until January, 1880.

Our Office Table.

A PAPER dome has recently been made, according to plans by Prof. Greene, of Troy, N.Y., for an astronomical observatory which has been erected for the Rensselaer Polytechnic Institute. It is a hemisphere 29ft. in outside diameter. The framework consists primarily of a circular sill, which forms the base, and two semicircular arch girders (parallel) spanning the dome. These are of seasoned pine. The paper covering is made in sixteen equal sections, their bases on the sill and their extremities meeting at the top; the framework of each consists of three vertical ribs of pine meeting at the apex. The paper is about one-sixth of an inch thick, and is as compact in structure as the hardest wood. A 4ft. opening between the arch girder is covered by a shutter (also of paper, on a wooden frame). The weight of the dome and its appurtenances is about 4,000lb. It is supported on six 8-in. balls rolling between grooved iron trucks. No machinery is used to move it.

THE Markets Committee of the Court of Common Council have drawn up a report recommending the construction of a new fruit, vegetable, and flower market for the City, at a cost not exceeding £30,000. The City Architect has prepared plans and a model, estimating the cost at £56,000, but the committee thought that a design of a less expensive character would meet all the requirements. The site extends from Charterhouse-street to Snow-hill and from Farringdon-road to the London, Chatham, and Dover line. All the excavations have been performed, so that the basement can be proceeded with. To form the approaches, King-street has been widened on the northern side, a new street from King-street into Charterhouse-street, and another new thoroughfare from this street to the junction of Snow-hill and Farringdon-road, have been made, and part of the London, Chatham, and Dover line has been covered in. The matter now awaits the Common Council's approval of an agreement to be entered into by the railway company and the Corporation. This market, when complete, will be the last of the series designated in the Act as the London Central Markets—viz., the Meat Market, the Central Poultry and Provision Market, and the Central Fruit, Vegetable, and Flower Market.

THE first ordinary general meeting of Mr. Ruskin's Company of Guild of St. George was held in Birmingham last week. The company was formed for the purpose of buying land in England, and thereon to train into the healthiest and most refined life possible as many men, women, and children as their land can maintain in comfort. The vital principle of the guild is that whatever profit is made out of the management of the land is to be applied to the comfort and welfare of workmen themselves. Alderman Baker presided, and a letter was read from Mr. Ruskin, in which he said, "I never contemplated any legal difficulties of the kind I meet with, and I entirely decline any further responsibility in such matters. The office of master, as defined in *For's*, is one of authority over persons voluntarily rendering obedience to great principles, and not authority enforced by law as at present constituted. For all the organisation of the Guild a clerk or secretary must be appointed to be responsible with directions from solicitors, for I am virtually dead to such business." A report from Mr. Ruskin was read stating that the Guild had estates at Sheffield, Bewdley, Cloughton, Mickley, Barmouth, and £500 vested in consols.

THE REV. J. B. STROTHER, formerly of St. Mary's Steps, Exeter, and now of Shaugh Prior—a remote parish upon the western borders of Dartmoor—has recovered the unique old font cover that formerly crowned the ancient moorstone font at Shaugh Prior Church. The font cover was found in an old linhay, or barn, the greater part broken and rotten, terribly damaged, and apparently quite beyond repair. Under the superintendence of Mr. Harry Hems, it was conveyed to Exeter. The crowning finial, which seemed altogether lost, was found in another house, adorning a rural chimney-corner. It consisted of a headless and handless Bishop, clothed in full canonicals, and carved in a spirited manner. The cover is now restored, and presents its original appearance as it was when, in the middle of the sixteenth century, it was originally

placed upon the font. Of spiral form, its place is a permanent one upon the font, and under no circumstances should it be removed. When baptism is administered, the sides of the lower portion work on hinges like wings, exhibiting the font bowl within; and in this baldachino-like canopy, the child is held and christened. No other example of such a cover is to be found in Devonshire, nor in any church in the West of England whatever. A few similar instances do exist of this odd arrangement, but they are nearly all in the Eastern counties. At East Malling, near Maidstone; at Tiechurst, at Walpole St. Peter, at Trovington, at West Walton, at Bramford, at Fringringhoe, near Colchester, and one or two other places, there are examples of like construction. The Shaugh Prior cover stands between 8ft. and 9ft. high, and is made of oak. It is octagonal in plan, and in its construction consists of three several stages. To the height of 3ft. it rises perpendicularly, each cant being filled with delicately carved running ornament, and surmounted by an enriched cornice; the diameter then lessens, and for another couple of feet or so it again rises perpendicularly, the angles being ornamented by carved work, whilst the eight corners have pinnacles, each surmounted by carved figures of priests in attitudes of prayer and adoration. Above this, the cover assumes a spiral form, the spandrels between the ribs being carved with pierced ornament of curious detail. The whole is surmounted by a mitred bishop, holding a crozier or pastoral staff in his left hand, and having the other raised in the attitude of benediction.

THE death is announced at the age of 76 of Mr. William Leslie, of Nethermuir. The deceased, who was a native of New Deer was a self-educated man, and well known in the Eastern Highlands for his ability as an architect and his enterprise as a railway contractor. His greatest work was the designing and construction of Duurobin Castle, Sutherlandshire, built in 1845-9, at a cost of £120,000. Forty years ago he built a tower to Aberlour House, on the banks of the Spey, and he also executed a number of important works in Aberdeen. He was a member of the firm of Macdonald and Leslie, who first started the granite-polishing trade of Aberdeen. As a railway contractor he constructed the Deeside, Buchan and Forfar, Devon Valley, Perth and Dunkeld, and Forfar direct railways. In 1872 he acquired the estate of Nethermuir in his native parish, at a cost of £63,000. He was lord provost of Aberdeen from 1869 to 1874.

THE LIVERPOOL ENGINEERING SOCIETY held its usual fortnightly meeting on Wednesday evening last. Mr. M. E. Yeatman, M.A., President, occupied the chair. A paper on "The Design and Construction of Sewers" was communicated by Mr. Graham Smith, past President. In opening his subject he remarked that sewers should not only be constructed in a manner to carry with despatch to the outfall the sewage which might find its way into them, but they should likewise be built in a manner such that no portion of the sewage should percolate through them into the surrounding earth. Cholera, for instance, might be spread indefinitely by matter discharged from the stomach or bowels of a cholera patient gaining access to any source of water supply. He quoted the General Board of Health returns to show that zymotic diseases largely exist and are much due to improperly constructed sewers and imperfect drainage arrangements. The question of the proper forms of sewers to be adopted under various circumstances was dealt with at some length, and the author advocated the circular section when a large and constant flow could be depended upon, and the egg-shaped sewer when a variable flow had to be accommodated, as the smallness of the invert increases the scouring action of a small quantity of sewage, whilst the increased size of the upper portion provides for any augmentation of flow. He considered that the success or non-success of any system of drainage depended upon the manner in which details were arranged. These questions, and such others as the ventilation of sewers and the materials employed in their construction, were fully considered.

THE *Times* and other daily papers of the 26th ult. published the astounding information that "M. Eugene Millet, the Archbishop who restored Rheims Cathedral and St. Germain's, is dead."

M. Millet was an architect, and did not belong to the clerical order, though his connection with Rheims Cathedral and other ecclesiastical buildings throughout France, may have led to the mistake. He restored the Palace of St. Germain, now fitted up as a museum, and was one of the first who followed M. Viollet-le-Duc in his studies of the ecclesiastical architecture of the country, and subsequent practice in the restoration of the ancient Medieval building of the country.

THE Adelphi Theatre has undergone a thorough renovation, under the immediate direction of Messrs. Gatti's architect; Mr. Green Chadwick, of Parliament-street. Knowing the dingy monotony of the theatre before its decoration, we can say that Mr. Chadwick has made this popular and cosy little house still more attractive. The structure was in the Italian Renaissance style, but the interior suffered from a tawdry kind of decoration. The effort made has been to adapt the new colouring and decoration to the style of architecture, and chiefly to make it assist in giving size and scale to the interior. Generally we observe that the scale of colour has been reduced in tone, a vellum and a light blue being the predominant tints, employed with a liberal use of gilding in the gallery fronts and details. The lighting also has been arranged so as to destroy the effects of shadows, and we observe that bracket lamps, in pairs, have been placed on each side of the pillars of the auditorium, and a crystal chandelier by Messrs. Defries, is suspended over the latter. An ingenious mode of giving apparent height to the theatre has been adopted in covering the circular level soffit of ceiling above the gallery with a light striped paper, the stripes being arranged to radiate from the domed centre; the effect below is to make this flat, annular portion of ceiling appear conical or raised, after the manner of a tent. The domical ceiling over the auditorium is relieved in the lunettes or panels with a series of subjects representing the "Golden Age," executed to imitate fresco by J. M. Allen, Esq.; and the vestibule to the Royal box has its ceiling decorated with a symbolic design, "Innocence." We notice, too, new curtains to the private boxes. These are made of a rich gold-coloured satin, the edges being of peacock blue velvet. The boxes are lined with a light-blue satin cloth, with vertical stripes of vellum-coloured material, edged with a gold moulding, the effect of which is rich and to give height. We observe, also, the boxes behind the dress circle have been removed, and we are told the acoustical effect has been improved thereby. Other alterations have been made in the upper gallery, by which the comfort and control of the occupants of this part and the amphitheatre will be secured. We dislike the pattern of the paper to the gallery ceilings, which hardly agrees with the curvilinear surfaces; but we notice a good dark dado paper to the passages and stairs, imitating stamped leather. The decorations have been carried out by Mr. Crossley, of Newell.

CHUBB'S

WROUGHT IRON DOORS,

Fire and Thief-Resisting Strong Rooms, Safes, and Iron Linings.

CHUBB'S PATENT LOCKS.

THREE PRIZE MEDALS

And Honourable Mention at PARIS EXHIBITION, 1875.

Illustrated Price Lists post-free.

CHUBB & SON, Makers to the Bank of England, 128, Queen Victoria-street, St. Paul's, E.C., and 63, St. James's-street, Pall Mall, London.—[ADVT.]

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of FEVER, BILIOUSNESS, SMALL-POX, SKIN DISEASES, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—[ADVT.]

Roofing Slates.—Reduction in prices! Send for price list to F. W. B. ASH & CO., ROYAL SLATE MANUFACTURE, Conway, before ordering elsewhere. Slate slabs, cills, hearthstones, ridges, cisterns, and all other kind of slate work very cheap.—[ADVT.]

CHIPS:

The contract for building a Wesleyan chapel at Perranwell, to hold 600 people, together with a schoolroom and class-rooms, has been entered into with Mr. John Blight, Redruth, in the sum of £1,750. The style is Early English Gothic, and the plans have been prepared by Mr. Hicks, of Redruth.

An exhibition of the drawings of the late H. Dawson will be opened at the Fine Art Society's galleries, 148, New Bond-street, on March 3. It will consist of some two hundred sketches and

drawings which have never been previously on view. The proceeds of the exhibition, which will only remain open until Easter, will be devoted to the Artists' Benevolent Fund.

A scaffolding is now in the course of erection in front of Ipswich town hall, to restore the cornice, &c., as a cantilever fell down a few days since, killing a young man. The town hall is a large Venetian structure, built about a dozen years since from the designs of Messrs. Bellamy and Hardy, of Lincoln.

At a public meeting held in the town hall, Waterford, last week, the mayor in the chair, it was resolved to open an Art Loan Exhibition in the city on the 1st of May next. A guarantee fund was opened in the room, when nearly £100 was subscribed.

The Church of St. Paul, Poole, is about to be enlarged and improved at a cost of £3,800 from the designs of Mr. G. R. Crickmay, of Weymouth. The proposed works include the throwing out of an apse and the addition of side galleries, and 200 additional sittings will be provided.

The Littlehampton Local Board have instructed Mr. Grantham, C.E., to prepare plans for a water supply for a present population of 6,000, with powers of extension for one of 10,000.

The Billericay Highway Board have accepted the tenders of Mr. John Cross, of Hutton, for the erection of foot-bridges at Hutton-wash and Meringtons.

The Hunstanton Cliff Company have accepted the tender of Messrs. Bardell Bros., contractors, for carrying out sea walls, shelter, and other improvements at Hunstanton. The works will be commenced in the spring.

The Society of Arts has just sustained a severe and sudden loss by the death of its well-known and greatly respected secretary, Mr. Peter Le Neve Foster.

A public laundry has just been erected in the Bridport-road, Dorchester, for a private company. Mr. G. J. G. Gregory, of Dorchester, was the architect, and Messrs. Gay and Sons the contractors; the cost of erection was £1,500.

Mr. George Fawkes, who had been town surveyor of Cricklade for 26 years, died last week.

Darsham Church, East Suffolk, was reopened on the 12th inst., after having been reseated and otherwise restored. The work was superintended by Mr. S. Brooke, of Croydon, who carried out in detail the plans prepared by the late Mr. E. Hake-well, architect, of Great Bealings. Mr. H. Mountain was the builder.

A watchmaker in Ayr has left the whole of his estate, amounting to about £10,000, to rebuild the bridge in the town which was rendered famous by Burns as the "Auld Brig o' Ayr."

A new lodge is in course of erection at the eastern entrance to Kingston Lacy Park, near Wimborne, from the designs of Mr. T. H. Wyatt. It is Italian in style, and in keeping with the mansion, built about 1663. Mr. A. H. Green, of Blandford, is the builder.

The French Government has, through the Minister of Public Instruction, conferred the distinction of Officer of the Academy on Mr. G. Tinworth, designer of Doulton ware, in recognition of his services to public instruction and to the Universal Exhibition.

The Todmorden Local Board last week accepted tenders, amounting in all to £2,103, for the erection of a new town hall.

The Essex Church Building Society have recently made the following grants in aid of church restorations:—Black Notley, £50; White Roosting, £40; Stanway, £60; and Wimbish, £30.

New shops have just been completed at the corner of English-street and the Victoria Viaduct, Carlisle, for Messrs. Johnston Bros. Messrs. Hetherington and Oliver were the architects.

Thomas S. Derham, general merchant, of Leeds, has filed a petition for liquidation by arrangement. First meeting, March 13, at Calverley Chambers, Victoria-square, Leeds.

Mr. Edward Rundle, for many years architect and surveyor for the Duke of Bedford's Tavistock estate, has been appointed steward of the same estate.

Memorial stones of a new Primitive Methodist chapel have been laid at Heworth Colliery Village, near the Felling. The plans have been prepared by Mr. Jamieson, of Belle Vue-terrace, Gateshead; and the contract has been taken by Mr. Thomas Dixon, of Windy Nook. The building will be of stone, and that the character will not be very expensive may be gathered from the fact that it is proposed to seat 220 persons at a total cost not to exceed £300.

A new church room, built on the western side of St. Martin's church, was opened at Dorking on Monday. The plans were prepared by Mr. W. R. Hawkins; Messrs. Goddard, of Farnham and Dorking, were the contractors; and the work was carried out at a cost of about £1,100, under the superintendence of Mr. Dibble.

Roskelton Episcopal Church, Monbraith, in the diocese of Leighlin, was reopened on the 21st inst., after restoration, including the substitution of benches for square pews, and the replacement of pulpit and reading-desk by more modern ones.

A donation of £20 has just been received from the Goldsmiths' Company, for technical education, at the Royal Architectural Museum.

Messrs. H. and J. Mabey, of Westminster, are the sculptors of all the carving at the new buildings in the Temple, which we described last week. The models were also prepared by Mr. H. Mahey.

The Town Council of Margate have decided to purchase the water-works supplying the town for £59,000.

The East Grinstead Sanitary Authority have received the sanction of the Local Government Board to the borrowing of £13,000 for carrying out a scheme of drainage, and have accordingly invited tenders for the execution of the work.

In the 34th annual report of the Newcastle and Gateshead Water Company, presented yesterday, it is mentioned that more than 12 miles of mains and pipes have been laid during the past year, and that at the present time a large new reservoir is being erected at Swinburn.

School of Art classes have just been formed at Crewkerne.

The tender of Messrs. Guynan and Son, of Carburton-street, has been accepted for the supply of the blinds and fittings at the new school buildings erected at Sittingbourne for the Borden School Trust.

In our last issue we omitted to mention that

the whole of the principal rooms in the Reform Club, Liverpool, were warmed and ventilated by means of Shillito and Shorland's patent Manchester grates.

The tender of Mr. Alfred Groves, of Milton-under-Wychwood, Oxon, has been accepted for the rebuilding of Little Rollright Bridge, for the county of Oxford, under the superintendence of their surveyor, Mr. H. J. Jollit, St. Aldate's, Oxford.

Considerable alterations and improvements to farmhouse and buildings at Barrington Down Farm, Gloucestershire, for Mr. R. H. Hurst, are about to be carried out, and new cottages erected by Mr. A. Groves, Milton-under-Wychwood, Oxon.

St. Augustine's Church, Norwich, which has been temporarily closed for restoration, was reopened on Sunday. The old vestry, which occupied the south-east corner of the church, has been taken down, and a temporary one opened out under the tower at the west end. The architect was Mr. R. M. Phipson, and the builders were Messrs. Downing and Son, of Pitt-street, Norwich. There are still several things needed to make the restoration of the interior complete.

A school of art has just been re-established at Bridgwater, with Mr. Davis as head master.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Arts. Cantor Lecture No. 3, on "Dwelling Houses: their Sanitary Construction and Arrangements," by Dr. Corfield, 8 p.m.

Society of Engineers. Paper on "The New Pits and Hauling Machinery for the San Domingos Mines in Portugal," by J. Bernhays, 7.30 p.m.

WEDNESDAY.—Society of Arts. "The Social Necessity for Popular and Practical Teaching of Sanitary Science," by J. J. Pope, M.R.C.S., 8 p.m.

British Archaeological Association. Dr. Phené on "The Cave of the Oracle of Delphi," and C. W. Dymond, C.E., on "The Stone Circle at Gunmerfeld," 8 p.m.

THURSDAY.—Society for the Fine Arts. Lecture on "The Art Decorations of the Stage," by W. J. Allen, hon. sec.

FRIDAY.—Society of Arts. "The Plants of India adapted for Commercial Purposes," by J. R. Jackson, of Kew Museum, 8 p.m.

Institution of Civil Engineers. Paper on "The Interlocking of Points and Signals, and the Electric Block System," by George D. Marston, Stud. Inst. C.E.

HELLIWELL'S Patented NEW SYSTEM

OF AIR & WATER-TIGHT IMPERISHABLE GLAZING. All Woodwork is covered, and no outside painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

"It is suitable for Railway Stations, Mills, Weaving Sheds, &c., but is specially applicable to Conservatories, Plant Houses, and Orchard Houses, and we should be very much inclined to try the system. It is certainly worth looking to."—*Builder*.

"And will, in our opinion, supersede any other similar system before the public."—*Birmingham News*.

"It seems to meet the end in view more nearly than anything we have seen yet."—*The Field*.

"Dear Sir,—I cannot see what testimonial you can require from me than the fact that I have taken off all my putty glazing and removed Kendle's work to replace it with yours; any one seeing the two systems would say that yours is far the superior, and that nothing yet out can touch it.—Yours, W. R. PARRSON. T. W. Helliwell, Esq., Brighouse."

For Estimates, Drawings, or Particulars, apply to the Patentee, T. W. HELLIWELL, Brighouse, Yorkshire; or, 19, Parliament-street, London.—[ADVT.]

CHAPPUIS' PATENTS

FOR

REFLECTING LIGHT.—DAYLIGHT REFLECTORS

OF EVERY DESCRIPTION, ALSO

ARTIFICIAL LIGHT REFLECTORS.

P. E. CHAPPUIS, Patentee. Factory, 69, Fleet-street, London, E.C.

N.B.—DIAGRAMS AND PROSPECTUSES ON APPLICATION.

THE BUILDING NEWS.

LONDON, FRIDAY, MARCH 7, 1879.

WATER-COLOUR DRAWINGS AT THE DUDLEY GALLERY.

THOSE who are admirers of skilful drawing and refined bits of colouring will not fail to enjoy the newly-opened Exhibition of Water-colour Drawings at the Dudley Gallery. There is nothing grand or ideal in the collection; we did not see one strikingly large or alluring picture on the walls, but the collection is made up of many pieces inspired by natural scenery and the commoner incidents of life, which please if they do not enthral the visitor. Rural and coast scenes, and a variety of studies of home life in which the tenderer emotions are chiefly concerned, comprise the larger number of works this year, though in these comparatively humbler efforts of the artist we meet with not a few admirable for their execution, their delicacy of drawing or colour. The sensational, whether it be in theme or treatment, is noticeably absent. Taking the order of hanging—we may here complain of the number “skied,” or placed too low for inspection—“The Young Wife” (8), by Ellen Clacy, is more remarkable as a misnomer than for anything characteristic, as all the artist represents is a young lady examining a piece of old china in a window, while the rest of the composition displays a goodly array of blue china in a hall recess. The title of “Curioso’s Wife” would be more appropriate. In “The Prayer,” Mr. N. Cipriani gives us a clever drawing of a dark row of stalls, apparently from some Spanish church. In one of them kneels a suppliant. Mr. S. T. Whiteford’s “Church of St. Satiro, Milan,” is forcible in colour; a vigorous handling of foliage is Mr. W. S. Addison’s “Marsh Marigolds” (19). There is a freshness in the picture, which is executed in a massive style with body colour freely used. No. 21, “Goring-on-Thames,” by Mr. A. C. Bell, is a delicately-handled landscape, although the treatment is broad. Truthful as a transcript is Mr. B. N. Spiers’ picture called “A Corner of My Study” (24), in which a few leather-bound books and an ink-bottle make up a modest but by no means inexpressive subject. Mr. Ernest A. Waterlow in his “Rear-Guard of the Flock” (33) has also chosen a simple rural scene. A girl with child on her back is driving a flock of sheep. The road, with its pools of water, the dark foliage and the sunset sky, the figures and the sheep are all conscientiously drawn. “Venice in June” (34), by Mr. H. Goodwin, is a gaily-coloured view of a scene painters never tire of depicting. For bold and truthful rendering of Highland cattle we commend Mr. J. Richardson’s work, “A Highland Mother” (39), while marine painting is well represented in Mr. Goddard’s “Hurst Castle, Hampshire” (40). As architectural sketches, the contributions of Mr. Phené Spiers leave little to be desired. His “Old House, Rye,” a timbered ruin, is hung too low to do it justice; but the most successful sketch is “Gloucester Cathedral from the South-east.” Mr. Spiers is certainly a master of sketching in colour; his washes are clear and transparent, and in the sketch before us there is a charm in the manner in which the elaborate detail of the tower and Late east window is expressed by a warm light shadow tint without an over-laboured execution. “Tintern Abbey from the South Aisle” (199), and the “Bishop’s Palace, Wells” (527), with its charming oriel, are also pleasing studies. We cannot pass by Mr.

W. T. Richards’ powerfully-coloured piece entitled, “Twilight—Coast of New England” (52). The light on the water, the rocky headlands, and the general tone of colouring make a highly effective scene. For figure-drawing broadly coloured, Miss Beresford’s “Under the Convent Wall” must also be mentioned, simple as the subject is. We notice, too, Mr. Egerton Hine’s “Tin Ghant, Whitby” (70); Mr. J. Moore’s “Lord Leveson” (72); Mr. McFadden’s “Roman Arch Bridge, New Forest”; Mr. F. C. William’s “Lynn Idwal, North Wales” (75); excellent subjects, all characterised by masterly execution—the latter a skilful rendering of mountain and mist. A kind of droll humour is depicted in Miss Kate Greenaway’s “Prissy” (79); a demure-faced little girl dressed in a sage-green frock, with white cross-over, wide brimmed green hat, standing against a wainscotted background; the same artist’s “Morning Call” (136) exhibits another study of a girl clad in similar antiquated attire—a red cloak, her mamma’s muff and bonnet, seated on a high chair. The precocious and sober countenance of the little mimic is as cleverly drawn as the subject is comical. One of the most attractive pictures is the work of another lady artist, Eliza Walker (95). A young lady in a brocade dress of golden hue, holding in her hand a black fan, stands before a pier glass; the reflections of face, the rich-painted china vases on the mantelshelf, and the hawthorn blossom are faultlessly painted, and the title is cleverly realised. The revival of the old costumes of the time of the early Georges has been eagerly turned to account by the depicter of manners. Thus, Mr. F. Slocombe’s “Scrap Book” (109) is a girl dressed in the low, short-waisted dress of our grandmothers, seated in a dingy room of old-fashioned furniture, a cat being her solitary companion. The screen and accessories are clever. “Sweet Seventeen” (116) hardly realises its name. The subject of the picture is a young girl dressed in muslin, with large hat and blue sash. The expression is rather that of a spoilt child than a young maiden, but the attitude is easy and graceful, and the basket of fruit in her hand, the fruit-laden wall behind, and the general colouring are refined and natural. The artist is Mr. E. S. Guinness. Mrs. Victoria Hine’s “Old Houses, Sandwich, Kent” (118), is a picturesque group of brick gables truthful in colour. A striking picture of sea and storm in their grander moods is called “The Surf-beaten Shore” (135), by Mr. G. L. Hall. As a study of cloud and atmosphere, the artist has shown unmistakable power over his pencil, but Mr. Hall is an adept at effects of this sort. Of an intensely natural style of execution is Miss Alice Havers’s picture (129)—

“The kine, the kine, are onward going,
As o’er the hills the winds are blowing,
They wander onward, ever lowing.”

Few would stop, perhaps, to look at so commonplace a subject as a few cattle wending their way over a bleak moor, but the drawing is very faithful. More inviting in its theme is Miss Kate Sadler’s “Satisfaction” (153), an old monk seated engaged in illuminating a missal. The artist has seized a moment of serene satisfaction in the countenance of the old recluse, and the china and green dresser are cleverly introduced. Rich toned, and striking for its pleasing face, is Catherine Atkins’s “Reaper” (176), painted with considerable feeling and tenderness. Mr. A. B. Donaldson’s “Leycester Hospital, Warwick,” is a quaint courtyard, with its galleries of timber parget, but harsh in colouring. Another very fine coast scene is C. Davidson’s sketch from the “Cornish Coast, near Tintagel” (185); a bold piece of colouring, with its verdure-clad cliffs, and its green and purple-

hued sea. Mr. Fitzgerald’s “Return from the Mask Ball” (187), is a frenzied idea cleverly worked out. Mr. G. D. Leslie, R.A., is always happy in his studies of character. “Curiosity” (194), is a pleasing incident that tells its own story. A little girl is peeping into a wardrobe or cupboard. The drawing of the figure, on tip-toe, clad in a white dress, the arms and expression, are exceptionally skilful. Another piece, entitled “Security” (211), by H. Stacey Marks, R.A., cannot be passed by. The old chest, of late French or Flemish, and the drawing of the old man, keys in hand, are full of meaning, and conveys the idea the artist has sought to produce. “The Manse Gate” (235), by Catherine Sparkes, is excellently conceived. The figure of the rosy girl descending the steps, the cool green background setting of the garden, the half-reflected light on the wicket combine to produce a very pleasing picture.

There are several very excellently-drawn subjects that come within the broad designation of *genre* and “common life.” Of these we can only name Mr. E. Jennings’s “Suburban Gardens” (223), a grey-toned picture of winter with the ordinary suburban surroundings. “A Surrey Hayfield,” by Mr. Slocombe, clever in the light falling on the hay; “London Shoeblacks” (243), by E. Roessler Franz; “An Afternoon’s Enjoyment,” a clever study of cattle; “The Hour of Recreation,” by C. Cabianna (271); “The Thames at Battersea,” 1879, by Arthur Severn (287), a rendering of grey mist and rain such as Londoners only know; “Three Merry Men are We,” by F. Dadd (297); “Breakers on a Reef,” very clever in the reflected light on crest of waves and the misty effects, by W. T. Richards (295); “A Rough Day in the Channel,” by H. Anelay (299); “Weeds,” by A. Parsons (319); “Contentment” (320), by J. Knight; “A Picture of Open Common” (322); “Waiting,” by G. Knight (332); “A Duet in Low Life” (341), by A. Ludovici; “Japanese Interior,” “Peasant Life in the Campagna,” by E. R. Franz; a sketch of a “Sandy Shore” (436), by C. J. Barraud; “La Plus Sage de l’Ecole,” and many others on the screens, such as Mr. Addison’s “Coppice,” “Long Ago,” by C. J. Atkins; “Recreation,” by C. A. Smith; “From My Window,” P. Norman (578). Mr. Hanbury’s “Side Chapel of Church of St. Maria de Popolo, Rome” (252), does not do justice to the rich marbled interior, and the drawing is poor. Decorative in character is Mr. F. H. Jackson’s picture (269) from the text—

“Red roses fair,
To wreath my love that wanders here,” &c.

The conception is poetically worked out. M. F. Sutherland’s picture, “In the Mary Stuart Room, Hardwick Hall” (275), is a richly-coloured sketch of old chair and chintz. As a landscape, Mr. A. Hartland’s “Coming Storm, Cwm Bychan” is fine; and in another class of art, Mrs. Champion’s “Flowers for Our Lady’s Shrine” (374), showing a sister making a wreath, is tender and pathetic. “Perdita” (371) is a pretty conceit, allegorically-treated, over-florid, by Kate C. Hastings, while “Thinking” (388), by C. J. Atkins, is clever chiefly as a study of accessories, such as the china and the furniture. Catherine H. Sparkes’ picture illustrating Matthew Arnold’s “Judas” is forcible and dramatic; the “furtive mien” and “scowling eye,” the “red hair” and “tufted fell” of the poet are seized by the artist in his conception, and the galleon and crew are well drawn. A finely-painted coast-scene is Mr. Walter Severn’s “Trevalga Rocks” (387); the ripples of the sea and the rocks are bright and transparently coloured. “The Harbour Bar” (410), by G. L. Hall, is a clever conflict between black cloud and surf-beaten sea, and the picture has the depth of oil. Mr. P. Williams’ “Church of St. Stefano, Venice” (411), is, as a severe sub-

ject, massively handled; and "Enone" (420), is expressive study of features, delicately rendered, by Mary Mason. We have contented ourselves with a mere glance at the collection, which is a very numerous one. We cannot, however, omit to mention some charming bijou flower-subjects; Nos. 617, 571, 502, 196 are especially worth notice. The models for statuettes are worth inspection. Mr. G. Simonds' "Eros Victor" is a pleasing conception, while "Charley," by E. R. Mullins, is a model in which the qualities of simplicity and truthful technique are undoubtedly combined.

THE CARPENTERS' HALL BRONZE PANEL COMPETITION.

PRIZES were lately offered by the Carpenters' Company in this journal for designs to be executed in bronze for the panels in the basement pilasters of their new building now in progress of completion in London Wall. Before saying anything about the designs submitted, we may incidentally observe that the new structure is a massively treated, ashlar-faced building in the Roman style, the entrance front of which is towards the old Carpenters' Hall. Mr. Pocock, the architect, has adopted a bold columnar treatment in the façades. They are of one order, the Corinthian, and the columns rest upon a solidly designed basement, in which are sunken panelled pilasters of some projection. The main order is composed of three-quarter columns, above which the entablature breaks, the whole being surmounted by an attic and balustrading. In the inter-columnar spaces are pedimented windows set within relieving arches, and these are flanked by Ionic columns. Below the entablature, and between the capitals and keystones, the spandrels are enriched by festoons boldly carved. In the basement plain segment-headed windows appear, the jambs of which are relieved by a hollow and plain grooved enrichment. The angle pilasters to each façade are rusticated, and the four intermediate ones have deep moulded panels, the intention being to fill them with bronzes. These panels are 13 feet 6 inches high by 2 feet 4 inches wide. The competitors had to consider, not the principal order or story of the building, but the basement only; they had to prepare a design that could be cast, not carved; and, lastly, the scale of the work in its relation to the façade had to be kept in view. These conditions have, of course, been violated by many of the competitors, and there are only two or three designs that fulfil fairly the condition of suitability to position, only two that express cast work, while as regards scale only one of the competitors can be said to have thought of it at all. As a whole, the designs are disappointing. Taking them in the order in which they are numbered, Mr. Banks sends three alternative treatments, one showing a figure in canopy, with compass and shield below; another has a centre group of carpenters' tools, and a third a head; but the lower portion of each panel is filled with an unmeaning composition in a species of rococo, and there is in all three drawings a crowded effect. The chief fault, to our mind, is that the designs lack character, and they are much more suited for interior wood carvings in an Elizabethan hall. As full-size drawings they are otherwise creditable. No. 2, by Mr. J. Daymond, of Vauxhall (we believe the stone-carver engaged in the new hall), is represented by three cartoons, of which we much prefer the design showing an octagon panel with figures in relief in centre, the lower part being filled with a composition in which a pedestal and stem growing therefrom, with scrolls, are the leading elements. The other designs have centre medallions, charged with emblems and the arms of the Company, filled up at top and

bottom with foliage and scroll-work, the latter becoming subordinate. To both these the objection is that they do not fill the panels, and would be far more consistent in a flat or horizontal than in a vertical position. The conception, moreover, is sadly lacking in the architectonic character which ought to be primarily kept in view, and the artist's idea is more characteristic of stone-carving than cast-work. We cannot seriously discuss No. 3; it is beyond criticism. The artist (Mr. J. How) has conceived something more nearly approaching a huge *bon-bon* than anything else we can think of. It is, in fact, a reticulated cage, circular in plan, with the Company's arms in centre and a crown at the top, projecting from the panel. Design 4 represents a brawny artificer, with axe in hand, the other parts of panel being filled with oak foliage. The design is weak. We would simply make the remark here that a large figure is very questionably introduced in such a position. One of the best designs is No. 5, by W. H. Binger; its conception is more architectural, and the relief indicated better adapted for bronze than those of previously mentioned designs. An oval panel with a representation of the craft forms the centre, above and below which are emblematic compositions, the subjects being surrounded with a water-leaf moulding. The treatment is scarcely bold enough for the positions. Another clever design, by Messrs. Cox and Sons, is in too elaborate a style of Renaissance to suit the basement of a building, in which solidity of character has been aimed at. The artists send two designs; both have centre medallion subjects, one representing Egyptian artificers at work, another a Renaissance subject. The designs would be well adapted for interior decoration, but for the position intended there is a want of scale in the work and figures introduced in the lower compartments of panel. The next design, No. 7, exhibits a bolder and more characteristic treatment. The artist (Mr. Hugh Stannus) has not overlooked the essentially architectonic position and attributes of such a work; the design is suited to bronze bas-relief, and comes within the limits of cast metal ornamentation. In one of the designs there is a circular panel with a seated figure of "Industry," above and below which are emblematic devices in allusion to the craft are appropriately introduced. At the top is a cherub's head, and a scroll with "Honour God" inscribed. The branching cornucopias below form a pleasing filling-in to the panel, which is surrounded by an enriched moulding. We observe also in a sketch elevation indicating the relation of the panels, that the tablets are made to range with the rustications, and the lower ornaments are kept in low relief so as to be less liable to injury from rough usage, both desirable points. Another clever design is No. 8, shown by vigorously coloured brown drawings. The designs exhibit trophies of carpenters' tools suspended from heads, in the composition of which the author has shown more ingenuity in grouping than good taste. The heads are too large, and the trophies have a crowded and lumpy effect, and certainly indicate by the relief a carved rather than cast treatment, which are evident faults. In contrast to the last, Mr. R. J. Boreham adopts the idea of growth instead of pendulous ornamentation. There are vases at the base, out of which foliage springs; but the design lacks boldness, and is only suited for inside decoration. No. 10, in pencil outline, is carefully drawn, but, like the last, is weak in conception, and the ornamentation is much too elaborate for basement pilasters. In marked contrast is the next, by Henry E. Tidmarsh, of Hornsey Rise, a bold chalk design, showing a rigid stem-like composition, with suspended trophies, wanting in grace and connection. The lower parts of panels are left plain stone. No. 12 shows female figures in

niches, with trophies and arms at the top and sides. The design is only suitable for stone. There is one other design, but it is of quite an unsuitable character. From our remarks it will be seen there are only two or three designs which fulfil the conditions upon which alone a selection can be made. In every other case the scale of the decoration and the treatment are at fault. Nothing in the panels should detract from the sculptured ornamentation of the superstructure; on the other hand, the relief should be strictly architectural and suggestive of cast metal. No models have been sent, but the Company will have little cause to complain; some of the drawings are separately worth the prize offered.

THE HARVEY STATUE.

FROM a large number of designs received for a statue to Harvey, the discoverer of the circulation of the blood, three models have been selected by the Committee for further consideration, and these are now on view at the South Kensington Museum. The statue is intended to be erected at Folkestone, the native town of Harvey. But there is a national interest felt in the memorial to so celebrated a physiologist, and the adoption of a model at once appropriate and artistic is a matter of public concern. We have inspected the models in the picture gallery at South Kensington, and while it would be rash to offer an opinion as to the result of a competition out of which only three designs have been selected, we consider that a larger display of designs would have been more satisfactory. Without doubt the three models exhibited are works of considerable merit, and if these are the three best procurable we have no hesitation in deciding upon the one that appears to embody the most desirable attributes as an artistic work. We presume the letters placed on the three models indicate the order of merit assigned by the judges, and if so, we think the least satisfactory has been chosen. The model marked A shows the great Linnæan lecturer in a standing attitude, with a note-book in his left hand, his right holding a heart, as if in the posture of demonstrating as a lecturer. His head is bent downwards, and he wears a flat cap and a kind of Genevan gown over the conventional costume, which consists of the slashed or buttoned doublet, short breeches, and stockings, common in the time of Charles I. There is a want of repose and gravity in the figure, though the face is highly intellectual, and on the whole it must be said the attitude is not dignified enough for a statue. It is a mistake made by young sculptors to conceive their ideal in too realistic a spirit, and to emphasise the professional vocation rather more than good taste dictates. This appears to us the mistake in the conception of the artist here. The design B is in our opinion marked by more of the qualities of a good statue. The artist shows Harvey in an upright and dignified attitude, his left leg slightly advanced. In his left hand he holds a heart, while his right hand is pressed to his own, as if in intelligent outward expression of his thought. The head has been modelled from the portrait of Janssens, we are told, now in the College of Physicians, and is eminently thoughtful and handsome. The figure is dressed in a buttoned and trimmed doublet with deep collar, short trousered breeches, and tight stockings, a cloak being hung loosely from his shoulders. The beard is trimmed to a point, and there is a decidedly Spanish or Vandyke style about the costume. The shoes have rosettes. The face is open and benignant, and features particularly intelligent and expressive. Unfortunately, the yellow stained wooden pedestal detracts from the model as an artistic whole.

Design C is also a clever composition. The physiologist is shown similarly clothed, but the cloak is loosely thrown on a tripod behind, and the artist has evidently endeavoured to portray Harvey in the position of a demonstrator or lecturer, as he holds in his left hand a heart, and in his right, as if in the act of performing an operation, is a lancet or probe. Behind, at the feet, lies a dead stag, from which the operator has apparently extracted the heart he holds up in his hand. The expression is intellectual; but while there is considerable ease and dignity in the figure and its accessories, the artist has, we think, fallen into the error of giving us the anatomist rather than the great discoverer and physician. The pedestal of this design is far too elaborate, though more architectural. Panels, with wreaths and serpents, relieve the sides, across which are tablets with the inscriptions, "Born, Folkestone, 1st of April, 1578," and on the other side, "Died, London, 3rd June, 1657." We understand this design has elicited much admiration from many who are not critical enough to see that a carved pedestal invariably detracts from the sculptor's principal work. The pedestal has in this case found admirers. From the above remarks it will be noticed that we prefer in conception, grace of attitude, and expression, the design marked "B"; and we hope the judges will not lose sight altogether of the idealistic qualities in balancing the technical merits of the several designs. Nor is it too much to demand in a public statue of a great man such as Harvey that the skilful operator be subordinated to that of a far-seeing physiologist and benefactor of mankind.

ARCHITECTURAL GEOLOGY.—V.

PALEOZOIC OR PRIMARY ROCKS.

CARBONIFEROUS GROUP.—The series of formations which we have now to consider is one of the most important in this country on account of the numerous coal-seams which are found in it, from whence it derives the name of "Carboniferous," although the coal itself forms only a very small part of the series, which is made up of sandstones, clays, shales, and limestone, alternating with the seams of coal. Our present business, however, is with the stones and other minerals which the carboniferous strata yield for the use of the builder, so that we shall leave the coal altogether out of consideration. In this country the carboniferous strata are found in large isolated patches, to each of which the term "coal-field" is commonly applied; thus we have the Newcastle coal-field, the coal-field of Yorkshire, Lancashire and Derby, the Dudley coal-field, and the South Wales and West of England coal-fields, all of which have some peculiar feature. There are three principal divisions of the group in England and Wales; the upper strata in which coal is mostly found being called the "Coal-measures"; the middle, which consists of thick beds of hard coarse sandstone, known as the "Millstone Grit"; and the lower strata, which is composed chiefly of hard massive beds of limestone with occasional beds of coal, termed the "Carboniferous or Mountain Limestone." In Scotland the Carboniferous Limestone immediately underlies the Coal-measures; the Millstone Grit being wanting, thick beds of sandstone with thin coal-seams being found below.

Coal-measures consist of a series of clay or shale, sandstone, and beds of ironstone with seams of coal, a bed of *fireclay* being found under every coal-seam, which is extensively worked for the manufacture of firebrick. Large quantities of sandstone for building and flags for paving are obtained from these strata, especially in Yorkshire, Lancashire, and Durham, as well as in those of Scotland;

these sandstones are generally very hard and durable, although most of them are highly laminated. The Newcastle coal-field covers a large portion of Northumberland and Durham, and yields in its upper series an excellent sandstone for building purposes, which is quarried at Heddon, Kenton, Hexham, Elswick, and other places. The stone of Heddon is coarse-grained, and weighs 130lb. per cubic foot, that of Kenton has fine grains and weighs 145lb. per foot; it is much used for buildings in Newcastle, and flags are obtained from the upper beds. Limestone suited for building is found near Morpeth, and flagstones about Berwick. There are several quarries of building stone near South Shields, and the Pensher-stone, near Houghton-le-Spring, is much used for buildings in Durham, Sunderland, and other places in the county. Redgate-stone, near Wolsingham, is fine-grained, and was employed in Durham Castle. Near Gateshead, Bishop's-Auckland, and Hartlepool good building stones are also procured from the coal-measures.

In Yorkshire there are extensive quarries of sandstone and flags in all parts of the West Riding Coal-field, chiefly in the neighbourhood of Leeds, Halifax, Bradford, Huddersfield, Penistone, Sheffield, and Barnsley. The Park-spring stone, found near Leeds, is a heavy fine-grained stone weighing 150lb. per foot cube, and is much used for architectural work. The quarries of Harehill, near Leeds, yield a fine grit stone for building, and also slabs and landings; that of Rawdon-hill, which has a fine grit, has been used in the Town Hall at Leeds, buildings in the London Docks, and at Woolwich Arsenal. There are also good building stones from the quarries of Headingley, Staningley, and Potternewton, in the neighbourhood of Leeds. The quarries around Halifax and Elland yield good building stone, and large quantities of flags, landings, and paving stones. There are some hard and heavy stones of excellent quality quarried in the coal-measures near Huddersfield, at Longwood-edge and Crossland-moor, which is much used for buildings at Huddersfield and Manchester. A large quantity of red, brown, and blue building stone, flags, and roofing slates is obtained near Sheffield, and employed in local buildings. About the neighbourhood of Northallerton are quarries of stone which is much used for buildings in several large towns; also near Bedale and Harrogate building stone is obtained from the coal-measures.

In Lancashire this formation contains many quarries of stone in different parts of the country, about Burnley, Wigan, Bury, Rochdale, Knowsley, and Liverpool. The stone of the Catflow quarries near Burnley has a light brown tint, is very hard and compact, and well suited for architectural purposes. Landings and flags are obtained in the quarries, but they are generally inferior in quality to those of Yorkshire. The coal-measures of Derby yield a coarse grained sandstone, some of which is obtained at the Duke's quarry, near Cromford, and has been used in the Victoria Docks at London. In the Forest of Dean coal-field of Gloucester many sandstone quarries are worked, and supply materials for local buildings and for paving. In Monmouth there are quarries of building and paving-stone at Newport and Pontypool.

The Coal-measures of Scotland cover a great part of Ayr, Dumbarton, Lanark, Renfrew, Stirling, Fife, Edinburgh, and Haddington. They abound in grits and sandstones, of which there are many quarries about Edinburgh, that of Cragleith yielding a stone of great durability and hardness which consists almost entirely of grains of quartz, and weighs 146lbs. per cubic foot. The stone from the quarries of Binnie and Humber, which have a finer grain than the

Cragleith, are much used for buildings in Edinburgh. Fine grained building stones with paving flags are obtained near Stirling and Falkirk, and there are several quarries in Fife, at Dunfermline, Saint Andrew's, and Strathmiglo.

The clay-beds of the Coal-measures are developed chiefly in Yorkshire, Lancashire, Stafford, and Worcester, where they are extensively worked for the manufacture of firebrick, red and blue building bricks, roof and floor tiles, drains and sanitary ware. In Yorkshire there are works of this kind in the neighbourhood of Sheffield, Rotherham, Barnsley, Leeds, Castleford, Halifax, and Huddersfield. In Lancashire firebrick is made near Barrow-in-Furness, Bury, Todmorden, Staleybridge, and Blackburn; building-bricks, drains and tiles being manufactured near Manchester, Bolton, Warrington, Toxteth-park, Liverpool, Rochdale, Haslington, Whalley, and Wigan from the clay of the coal-seams. Firebrick is largely made in Stafford and Worcester at Stourbridge, Bilston, and Tipton; and the clay is made into terra-cotta, drain-pipes, bricks and tiles at Bewdley and Tipton. Blue bricks are also made near Tipton, Cannock, and Birmingham; building-bricks, tiles and drains at Walsall, Burton-on-Trent, Newcastle-under-Lyne, Kidderminster, Congleton, and Tunstall. In Salep the clay is made into encaustic tiles at Benthall, near Broseley, and into bricks, tiles, and drain-pipes at Shrewsbury, Ludlow, Whitechurch, Shifnal, Oswestry, and Bridgnorth. Beds of fireclay are also found in the coal-measures of Durham and Northumberland, about Newcastle, Morpeth, Durham, Sunderland, South Shields, and Darlington, where it is worked for bricks, tiles, drain-pipes, chimney tops, &c. In Cumberland it is applied to similar purposes at Whitehaven, Maryport, Thursby, and Ravenglass. In North Wales the clay is made into bricks and chimney tops about Wrexham, Hawarden, Mold, Ruabon, and Conway; and into firebrick in South Wales at Aberdare, Swansea, Cardiff, Merthyr, and Brecon. The Coal-measure clay is made into bricks and tiles in Gloucestershire at Cinderford, Coleford, Easton, Micheldean, and in the neighbourhood of Bristol; in Warwick red and blue bricks and tiles are made from it at Atherstone, Coventry, Tamworth, Nuneaton, and Kenilworth; and in Leicester it is worked for red bricks and tiles at Ashby-de-la-Zouch and Melton Mowbray. In the Coal-measures of Scotland the clay is largely used for bricks, tiles and drain-pipes near Edinburgh, Glasgow, Paisley, Blantyre, Coltness, Kilmarnock, Kilwinning, Bothwell, Stonehouse, Coatbridge, and Wishaw.

Millstone Grit forms a series of coarse quartzose rocks which crop out along the edge of the coal-fields of England and Wales, where it forms the foundation on which the coal-measures rest; in South Wales and the South-west of England it is known as the "Farewell rock" on account of the absence of coal-seams in this formation. It is chiefly developed in the West Riding of Yorkshire, and is conspicuous at Alston-moor, Swaledale, Wensleydale, Ingleborough, and Pen-y-ghent; also at Pateley-bridge near Harrogate, in the Plumpton rocks at Knaresborough, and the Ilkley crags near Bradford. The grit quarried at Gatherley-moor, near Richmond, is largely used for building purposes about Richmond and Darlington. In the neighbourhood of Leeds and Selby there are several quarries of a coarse grit known as Bramleyfall stone which is largely used about Leeds as a building stone, and has been employed for the Euston Railway-station in London. Near Huddersfield a heavy grit weighing 158lb. per foot cube is quarried at Scotgate-head, and much used for local buildings; there are also numerous quarries of building stone, flags, and roofing

slates in the same locality at Longwood, Marsden, and Saddleworth. In the neighbourhood of Sheffield the grit is quarried at several places for ashlar, walling, flags, sills, and steps. There are also several quarries of building stone and flags about Southowram near Halifax, and at Ripon a freestone is obtained which is much used for local buildings. In Lancashire the Millstone Grit yields good building stone near Bolton, Preston, Wigan, and Liverpool. In Derby it is quarried at Ashover, Buxton, Matlock, Rowsley, Wirksworth, Belper, Chapel-en-le-Frith, Derby, Duffield, and at the Duke's quarry near Crick, where a purplish green stone weighing 144lb. per foot is procured, which is largely used for bridges, galls, and docks. The stone of Darley-dale, near Bakewell, weighing 148lb. per foot cube is much used for buildings of a superior class. In Warwick a hard quartzose rock called the Hartshill-stone is quarried near Nuneaton for building and paving, having been indurated by contact with igneous rocks. A grit is obtained at Prudham near Hexham, in Northumberland, and is much used for buildings in Newcastle; and in Durham there are quarries near Barnard Castle, Darlington, Stanhope, and Wolsingham.

Carboniferous, or Mountain Limestone, is found in England and Wales underlying the Millstone Grit and forming the lowest beds of the Carboniferous series; in Scotland, however, where the Millstone Grit is generally wanting, this limestone lies immediately below the Coal-measures. It consists for the most part of massive beds of a bluish-grey crystalline limestone, which is generally too hard to be much worked by the mason, and is chiefly quarried for burning into lime, although some of it is capable of receiving a polish and being used as marble for decorative purposes. The scenery of the country where the limestone crops out is usually of a rugged description, forming the cliffs and combs of Somerset and the dales of Derby. Copious springs of water are obtained from this formation, owing to the fissures in the rocks. In the North of England the term "Scar Limestone" is applied to the formation, which is developed at Alston-moor, Ingleborough, Pen-y-ghent, Wensleydale, and Swalesdale; a narrow strip of it also skirts the slate of the Lake district and passes along the Vale of Eden; marble is obtained from it in the neighbourhood of Kendal, as well as lime and building stone. The Carboniferous Limestone presents the most characteristic features and great uniformity in the counties of Leicester, Derby, Gloucester, Monmouth, Salop, and Somerset, where it forms a great calcareous mass undivided by bands of clay or other beds. In Leicester it is dolomitic in character, and is quarried for making into lime at Breedon-hill, Ticknall, and other localities. In the neighbourhood of Bristol it yields marble for decorative work as well as good building-stone. Marble is also found in considerable quantities about Matlock and Rowsley, in Derbyshire; and limestone obtained at Hopton-wood, near Chatsworth House and Belvoir Castle. Hydraulic cement is made from the limestone which is quarried at Holywell, in Flintshire. In Scotland the Carboniferous Limestone is quarried in the neighbourhood of Edinburgh and Dalkeith for building stone and lime, and also at several places in Ayrshire and Fife.

In our report of Dr. Corfield's lecture on "Household Sanitary Arrangements" in the BUILDING NEWS of the 28th ult., we state "a model of an automatic fastener, invented by Messrs. Thompson and Sons, of Birmingham, was exhibited and explained." The name should have been "Tonks and Sons." The fastener in question is that referred to as "Patent Sash-opener and Automatic Fastener" in the advertisement which appears in our columns.

HOUSEHOLD SANITARY ARRANGEMENTS.—III.

IN his third Cantor Lecture, "On Dwelling Houses," delivered on Monday evening at the Society of Arts, Dr. Corfield concluded his remarks upon ventilating and heating apparatus, and commenced the consideration of water supply. To show how air could be admitted to a room without perceptible draught, an experiment was performed. Two little flags were hung in a line with the nozzle of a pair of bellows; when the bellows were blown they waved, the agitation being more marked when a tube was added to the bellows. One of Ellison's conical brick ventilators being placed before the bellows, with the small hole next the nozzle, scarcely any movement of the flags took place till the bellows had been worked for some time. A device invented by Mr. Stevens, in which a series of uniform perforations ended in little metal cup-mouths placed behind a wire grating, was applied to the bellows with equally satisfactory results. Such contrivances for admitting fresh air to rooms without draughts ought to be placed high up in the apartment, and not in the skirting board, as was too often done. Unless the fresh air was warmed by passing over heated pipes, it would be too cold to be admitted to the lowest level of a room. M'Ilaffie's valve was exhibited and explained, it being shown that it would admit fresh air unless the wind was too violent, when it would be self-closed. Some galvanised iron-louvre ventilators, which are adjusted by a key, sent by Hart, Son, and Peard, were also shown. Dr. Ball's ventilator had a delicately-adjusted valve (which in the exhibited specimen was out of order), admitting air to a siphon-like passage; it was claimed for the siphon that blacks would thus be kept out, and that air would be "drawn up" more readily; but the lecturer expressed grave doubts as to the possibility of the latter claim being sustained. There were two or three kinds of stoves or grates connected with ventilation. That invented by Captain Douglas Galton had all round it an air-chamber, into which fresh air was admitted from outside, and after being warmed, was passed into the room. By this means, 35 per cent. of heat from the fuel was utilised. A variety of this was the Manchester School-grate, one of the differences being that air was admitted in a vertical direction. The caution was given that the back of the grate and the flue, so far as they were in an air-chamber, ought to be of one casting; if a joint existed, sooner or later it would open, and air would pass from the flue into the air-chamber. Some slow-combustion stoves had a provision for heated air returning into the room. This air was always too dry, the modifying influence of the water vessel set upon the stove being comparatively slight, and the charring of the organic matter in the air caused the peculiar smell known as that of "cast-iron." Mr. Saxon Snell had recently invented a contrivance known as the Thermo-hydric grate. It looked like an ordinary open fire, having near it a boiler connected with a series of vertical hot-water tubes, which stand round about as a range of pillars. The water in these pillars is heated, and thus assists in warming the room; and between the tubes fresh air is admitted into the room, and is gently warmed by the contact. These stoves were found to be too cumbersome to be brought to the Society of Arts' room, but might all be seen at any time on presentation of card at the Parkes Museum, University College. The lecturer next referred to the future prospects of gas. He believed that gas would be more largely used in its proper capacity, that of a warming and cooking agent. It was possible that for a long while it would hold its own as a light, but he did not think we should continue to use coal in the ridiculous manner we do now. We burned coal directly, whereas from it not only could gas be distilled, but tar, carbolic acid, aniline dyes, salts of ammonia, and other increasingly valuable products were obtained at the same time. It was perfectly absurd to suppose that we could go on wasting all these substances in our fires. In every large house the mere dust and dirt created by open fires was equivalent to the employment of two servants. The gas companies ought to be alive to this, and let out for hire gas stoves for cooking, as they now do the meters; but he warned his audience that if gas were used for culinary purposes, the present service pipes would be insufficient. Bunsen's stove was the best for these purposes. The notion that a gas fire was more unhealthy than one of coal was a

mistaken one; if equal care were taken to remove the products of combustion, the one need be no greater nuisance, nor more deleterious, than the other.

The lecturer then took up the question of Water Supply. There were certain obvious characteristics which a drinking-water should possess. It should be clear, colourless, free from suspended matter, forming no deposit if standing, without taste or smell, and aerated. If any of these qualities were absent, the water might be dismissed as unfit to drink; but it might have all these characteristics, and yet be unsuitable, because contaminated by sewage. The suitability of a water could only be ascertained with certainty by a knowledge of its history, added to careful chemical investigation. Waters might be divided into hard and soft. To say which it was advantageous to use was a difficult question. The disadvantages of hard water in that it clogged up pipes with deposits, and that more soap was needed for washing, were obvious, and the popular prejudice that soft water was preferable appeared supported by facts, including its invariable choice by domestic animals: the Registrar-General had proved however that, other sanitary conditions being equal, there was no difference in the average mortalities of towns supplied with hard or with soft water. But hard water might be softened—on a large scale by the use of Clark's process, which consisted in adding lime to water already too largely charged with lime, but the milk of lime united with that already in the water and was precipitated with it as a carbonate of lime, carrying down all suspended matter in the water, and leaving it when seen in large masses of a peculiar bluish-green colour. A disadvantage of the process was that the deposition of carbonate of lime was somewhat slow,—an improvement was the Porter-Clark process, in which the precipitation is effected by lime in filtering the water. The proper supply of water in towns should be from 30 to 35 gallons per head, per day. Prof. Rankine had indeed fixed the latter quantity as a maximum, but he deprecated any set limit; if as much as possible were provided, a use could be found for it. Ancient Rome had a supply of 300 galls. per head daily, brought by three great aqueducts, and although these had been patched and tinkered up by successive Popes, it was still the best supplied of large cities. The further question arose, how a supply should be obtained? The rain was a source giving an exceedingly soft and well aerated, and away from towns a pure supply; if collected in and for rural districts, it was the best supply. In towns, however, the rainfall was so laden with soot, organic matter, and free acids as to be unfit for drinking until purified. In many places shallow wells were almost the only source, but were liable to contamination from cesspools and leaky drains. An economical mode of making these was by means of Norton's Abyssinian pipes, which could be connected together so as to supply a main. Again, springs or small streams could be impounded and brought into towns by conduits—the Roman plan. Incidentally the popular mistake that the Roman engineers did not know the use of the siphon was corrected, Dr. Corfield remarking that at Lyons the water was brought through three deep valleys by a series of leaden siphons. Further, towns might be supplied with water from the rivers passing through them, which rivers had higher up received the sewage of other towns. This sensible and cleanly method of supply was largely adopted in this enlightened nineteenth century. There was a town in England which took its water supply from a stream a mile below the point at which it discharged its own sewage—an example of a "circular system of supply" to be carefully avoided. A stream was said to be capable of self-purification, and that this could be supplemented by purification in the waterworks and houses, but this was mere sophistry. There was no river in England of sufficient length to admit of natural purification, and the danger even existed that purifying processes might be neglected at the place of intake—a peril which had been more than once exemplified in London. He appealed to the common-sense of the audience whether it was not better to use a water above suspicion than that from a river containing sewage, even if the latter were filtered, boiled and even distilled. Another source of supply was artesian wells, sunk to the subterranean reservoirs situated between the clay and impermeable rocks. This water was free from organic matters but normally hard. The Kent Company and part of

the New River Company's supplies were drawn from artesian wells, and were the purest in use in London. This artesian water could be furnished to the whole of London if the inhabitants had only consented to the double system of supply, for drinking and cleansing purposes, as projected a short time since. The great advantages of a constant over an intermittent supply were pointed out in cleanliness, freshness, coolness and readiness to hand; under the present intermittent system cisterns were, however, indispensable in London households. These were often made of lead, an excellent material for the purpose, but expensive. The dangers of lead for water conveyance had been enormously exaggerated; after a short time the lead was coated with an insoluble compound, and then only very soft or pure waters could act upon the metal. Slate cisterns were expensive and usually leaked after a time, when the plumber was called in and caulked the joints with red lead,—quite as poisonous as lead itself. For use on the ground-floor, where weight was no consideration, glazed stoneware cisterns were useful and cleanly. Galvanised iron was another useful and less ponderous material, upon which water had no action. Proceeding to consider water pipes, a curious specimen was shown of a lead pipe which had been recently taken up from the chalk near London, in which the metal had been eaten away by external moisture acting on the chalk. Lead pipes were sometimes lined with tin; but the remedy was worse than the disease, for water acted much more quickly on lead if another metal were present, as galvanic action was set up, and any crack in the tin lining was speedily a source of prejudicial decomposition of the metals. Varnishes for the interiors of mains were best avoided; many were useless and some mischievous, for one of these coatings contained arsenic. In conclusion, the lecturer showed the action of ball-cocks in regulating the supply of water to a cistern, the modes in which they work, and several recent improvements. In the next lecture the subject of Filtration will be taken up, and also that of the Removal of Refuse Matters by Dry Processes.

OUR COMMONPLACE COLUMN. GALLERY.

THE term may be applied to a corridor-like space or room, or, more technically, the floor of a building supported by columns, as the gallery of a church, chapel, or public hall. A gallery in a building for public speaking or in a theatre should be arranged so that the floor shall be sloped at such an angle that the occupants of seats in the back-row may see over those immediately in front. The appearance of columns immediately below the front of a gallery always has an unpleasant effect, and it is better to project the front over the line of support by cantilevers or coves. Many interesting samples of galleries may be found in the churches of Wren, and in the old Elizabethan halls. (See article on "Galleries" in the BUILDING NEWS and illustrations). For picture-galleries we refer the reader to those of the National Gallery, Royal Academy, the Grosvenor Gallery, &c., the chief point being the proportion of the cross section of the apartment, so that the rays of light may produce the greatest illuminating power on the side walls without unpleasant reflection.

"J. A." sends the following note:—Strictly speaking architecturally, a room may not be called a gallery except when its length is three times its width. A gallery whose dimension in length is considerable, will bear to be somewhat loftier than one whose dimensions are more curtailed in the length; but the height must not give the appearance of narrowness, and so resemble a mere corridor. "There is hardly anything in the interior of a building which lends itself so readily to architectural effect as a gallery, by giving lengthened perspective and vista. And when the gallery is formed into divisions, many fresh and rich combinations of form are obtainable." There is at Holkham, in Norfolk, a very beautiful gallery for statues formed by two octagons and a centre connected by open arches. The arranging of galleries tier above tier dates from the seventeenth century.

GARGOYLE.

Gargoyle, or gurgyle (from Lat. *gurgulio*, the throat-pipe), a projecting spout placed generally at the angles of a cornice to carry off the water. They were first introduced into England in the thirteenth century. They are usually in the

form of animals, birds, or human beings. Sometimes, however, they are quite plain. Their origin is somewhat doubtful, but they probably arose from the arrant superstition and mysticism of that age. By some they are considered as charms, or petrified sentinels, to guard against the intrusion of demons. Usually they are grotesque and very ugly; sometimes they are realistic. M. Viollet-le-Duc, speaking of them, remarks that gargoyles were introduced in the beginning of the thirteenth century. They may be seen in the cathedral of Laon, 1220. Many of them are masterpieces of Mediaeval sculpture. Towards the end of the thirteenth century gargoyles became more complicated, the human form often superseding the animal. In the church of St. Urbain, Troyes, may be seen a gargoyle in the form of an amply-draped youth holding a ewer. Gargoyles are common in the Ile de France, Champagne, and on the banks of the Lower Loire; they are rare in Burgundy, in the centre and south of France.—C. F. W.

GATE.

The size of gates depends upon the use to which they are put. Generally, 8ft. 6in. to 9ft. is allowed for width. There are various modes of framing, but the main principle to be observed is to throw the weight of gate upon the hanging-post by cross-braces. We have dealt with this subject in previous articles (see volumes of BUILDING NEWS for 1878). It is very necessary that the material, if wood, should be well seasoned, and the framing accurately put together, the tenoned rails being strengthened by iron straps at the angles. The hinging of gates is an important point, and to this subject we refer the reader. Sometimes the opening stiles run on friction bearers, which, for very heavy or wide gates, are necessary.

GEOMETRIC PROPORTION.

This is a method of designing buildings upon certain geometrical figures, such as the triangle, square, &c. It is well known that the Egyptians and Greeks both applied geometrical construction to the proportions of the plans, masses, and elevations of their halls and temples—a subject that has been alluded to by Aristotle, Vitruvius, Leonardo da Vinci, and various other authorities, ancient and modern. Viollet-le-Duc alludes to the proportions of the Egyptian and Greek structures as mainly founded upon a system of triangles; the subject has been largely treated of by the late Mr. Edward Cresy in Gwilt's "Encyclopedia," who divides the façade of a temple into squares, a certain number giving the width, and another the height. The subdivisions of columns, entablature, pediment, &c., are also proportioned upon this method. It is also agreed that certain proportions based upon the equilateral triangle were given by the mediæval architects to their works, and that the widths and heights of their churches were determined in this way. The sections of many of our cathedrals have been found to be determined by this triangle, and its combinations and subdivisions; the *vesica piscis* was a favourite symbolic figure so employed; and the solids and voids were regulated in the same manner. The square and its diagonal were also used in giving the proportions of plans and elevations in many instances. Salisbury Cathedral is based upon the equilateral triangle erected upon the plan. Winchester and York Cathedrals are also proportioned upon the same figure. We may refer to the works of Vitruvius, Cesare Cesariano, Boeckler, Hoffstedt, R. W. Billings's "Attempt to Define Geometric Proportions," a Mr. Kerrieh's paper in the *Archæologia* XIX., Mr. Pennethorne's "Geometric and Optical Principles of Architecture," &c. (See articles in BUILDING NEWS.)

GEOMETRICAL DECORATED.

This term is applied to the period of mediæval architecture in which geometrical forms in window tracery was developed from the previous Early English forms. It is really the transition from that style to the Decorated of the 14th century. Mr. E. Sharpe adopted this term in his nomenclature between the Lancet and Curvilinear, and assigns the period from 1245—1315.

GILDING.

"J. A." sends the following notes:—

Gilding, or the process of overlaying surfaces with gold. *Mechanical gilding*.—This relates to the application of leaf-gold to wood, stucco, and other plastic materials used to imitate wood-

carving. Process.—First, the surface is prepared with a layer of "thin white." This is composed of whiting and hot size. If the gilding is to be burnished, this is followed by a second coating of "thick white," which is made from the same materials as the "thin white." When these two preparations are completed, the whole of the surface is carefully rubbed down, smoothed off, and a coating of gold size is brushed over, after which it is allowed to dry, then levelled again as the leaf-gold is laid upon it. *Operation*.—The gold leaves are in succession dropped from the goldbeater's hook on to a cushion or pad, held in the hand of the workman, and are by the breath, flattened out on the surface, and cut into the required sizes. Thence the pieces are lifted and laid on the work by a sort of comb formed of delicate bristles, and urged close to the levelled surface of the ground by gentle puffs of the breath. When the gilding has reached a certain dryness it is burnished by an agate-burnisher. These portions are called "matt," and the other parts "burnished" gold. In oil gilding there is a slight difference from the above in the preparation of the surface. First, two or three coatings of thin white are applied, this being mixed with a little mellow clay, afterwards two or three coats of plain gelatine size, and last of all the oil-gold size upon which the leaf is laid.

Amalgam, or Water-Gilding.—Process.—In gilding of articles of metal, pure gold is first combined or amalgamated with quicksilver, by boiling the gold in five or six times its weight of quicksilver. The boiling mixture is poured into cold water, by which it loses a great deal of its fluidity, and it is then squeezed through chamois leather. The amalgam is now the consistency of stiff clay, has a greasy and gritty feel, and is in the most convenient state for being weighed out into the portions requisite for each respective quantity of work. The articles to be gilded are placed in a sort of "cage"; this cage is made in a cylindrical form, and is generally about 18in. in length, by 9 or 10in. in diameter; it is formed of coarse iron-wire gauze, supported by an external framework of iron, furnished with a solid iron door at one extremity. The articles under process having been placed in the "cage," the door is securely fastened; it is then suspended by its axle on two supports in an iron cylinder. The cylinder being previously heated by a coal fire beneath it to such a degree as to be red-hot over a large proportion of its exterior surface, the cage is introduced, and the doors of the cylinder closed. The hinder part of the cylinder is connected with a chamber and flue, so constructed as to carry off the deleterious fumes of the mercury. Steel and iron are gilt by being immersed in a mixture of nitro-muriate of gold with sulphur in ether or alcohol. By combining these liquids together, an alcoholic solution of gold is formed, from which the metal is precipitated by the iron or steel. Ivory or bone may be gilt by immersing it first in a solution of sulphate of iron, and afterwards in nitro-muriate of gold.

Encaustic Gilding.—This distinction is applied to the coating with gold porcelain or glass. Porcelain is gilt by the application of gold leaf during the process of manufacture, and fixed by that intense heat which confers upon this substance its enamel and glaze. Glass may be gilt by applying leaf-gold to the glass when wetted with a solution of isinglass.—J. A.

Two windows, designed and executed by Messrs. Powell and Sons, Temple-street, City, have been inserted in the chancel of St. Michael's Church, Lewes. The one at the north side represents St. Longinus the Centurion, who was present at the Crucifixion; and that on the south side, St. Michael having conquered the Devil, who lies at his feet in human form. The windows are to be considered as an extension of of the eastern one, on which is represented the Crucifixion.

The Dublin Central Tramways were officially inspected by Major-General Hutchinson, R.E., on behalf of the Board of Trade, on Saturday, and were authorised to be opened for traffic. The lines extend from Dame-street to Clonskeagh, and from Camden-street along the South Circular-road to Clanbrassil-street. Mr. R. W. Walsh was the engineer, and Mr. W. M. Murphy the contractor.

Everyone will be glad to hear that Mr. J. L. Pearson has been appointed to the office of architect and surveyor of the fabric of Westminster Abbey, vacated by the lamented death of Sir Gilbert Scott. The special works already commenced by Sir Gilbert Scott will be continued by his son, Mr. John Oldrid Scott.

PRIZE DESIGN FOR A SCHOOL OF ART.—DAIRY FARM PLANS.—
HADDON HALL, PART OF NORTH FRONT.—NEW HOUSE AT
EASTBOURNE.—NEW PREMISES OF THE ART UNION OF
LONDON.

OUR LITHOGRAPHIC ILLUSTRATIONS.

DESIGN FOR SCHOOL OF ART AND SCIENCE
BUILDINGS.

THE above design was sent in for the National Competition at South Kensington of last year, and was awarded a bronze medal. The subject was chosen in preference to others as being one more calculated to bring out the abilities of students. It will be seen upon reference to the plan that the building is divided into two wings or departments. The left-hand wing is wholly devoted to the requirements of a good-sized school of art, and includes all the rooms necessary for the various branches of art training. A head master's room, with studio, is provided, together with second master's, secretary's, and committee rooms, and an attendant's house. Staircases for the respective departments flank the south-east and south-west angles of the building. The front is supposed to face the south, and there being few class-rooms on that front, the greater part of light obtained would be from the north, east, and west, a south light being considered objectionable. The large lecture hall forms a central feature, and is emphasized externally. This hall would be common to both departments, and its dimensions show that it would serve for concerts, lectures, &c., it having separate access, and being somewhat disconnected from the busier parts of the schools. The right wing consists of a series of class-rooms, lecture-rooms, and laboratories, which make it suitable for scientific purposes. The plans themselves will fully explain the further details of the buildings. Externally, that treatment has been aimed at which would give most light and air together with a simple architectural effect. The materials proposed are white brick with stone dressings, the internal woodwork pitch pine or oak, the glazing generally plate glass, but of the large hall cathedral tinted in lead lights, and the roofs to be covered with Staffordshire tiles. The design is by Arthur Marshall, a student of the Nottingham School of Art, of which school Mr. J. S. Hawle, F.S.A., is the head master, and it was criticised in the BUILDING NEWS at the time the national competition drawings were on exhibition at South Kensington.

DAIRY FARM BUILDINGS.

THE principal object in this design being to obtain the most suitable position and best aspect for cow-house and covered cow-yard, with an economical arrangement for the preparation and supply of food; the former building is made to occupy nearly the whole of the south front. The covered yard in connection therewith and measuring 72 by 64 feet is sheltered on the west and east sides by other buildings. The roof of this yard is proposed to be constructed with wrought-iron principals of one span, covered with galvanised corrugated iron, by which means a flat pitch, but light and durable covering, is

obtained, and the danger from choked and overflowing flat gutters are to a great extent avoided, while greater facilities are given for the movement of cattle and the carting of manure, through the avoidance of intermediate roof supports. In actual practice a roof similar to the one shown, and for the same purpose, has been found to cost less than if constructed in the usual method of two or more spans. The shed centrally placed at right angles to the cow-house admits of cattle food being prepared and conveyed for use by tram truck with the least possible amount of labour. The steaming apparatus is placed in close proximity to the chaff-bin and root-cutter, and the meal boiler for piggeries convenient to the meal bins. The chaff-cutter would be placed on upper floor over the chaff-bins, the corn mill over meal bins and adjacent to granary, and the root-cutter on bottom floor, driven by a counter-shaft from the main shaft above. Piggeries facing south have covered courts and open yard; waggon and implement sheds are placed north and shelter the open yards. Straw for litter would be deposited in straw loft by an elevator, and from thence pitched through doorway into covered yard as required. A fixed engine and Cornish boiler are proposed to be used for driving the machines, and the shafting would be on upper floor.

HADDON HALL.—THE NORTH FRONT.

It would not be fitting to attempt a description of Haddon in a paragraph of the sketch. I may say that it was made on a frosty morning in January, and represents principally the exterior breaking up of the kitchen chimney.—W. R. LETHBRAY.—Amongst the sketches of details from Haddon Hall, which have been illustrated in the BUILDING NEWS, are the Woodwork, April 2nd and 16th, 1875 (Vol. XXVIII., pp. 372, 428); Chapel Seating, February 18th, 1878 (Vol. XXXIV., p. 158); and the Leadwork, August 30th, 1878 (Vol. XXXV., p. 210).

NEW HOUSE AT EASTBOURNE.

THIS very interesting little bit of domestic architecture was exhibited, by the view we publish to-day, at last year's Royal Academy Exhibition. The several details also included in our illustrations will at once explain themselves. Red brick and tiles were used for the walls and roofs, with cut and carved brickwork to the entrance. Mr. R. W. Edis, F.S.A., is the architect.

ART UNION FOR LONDON—NEW PREMISES, 112,
STRAND.

LAST week were published a general drawing, with plans and description, of this new building now in course of erection, from the designs of Professor E. M. Barry, R.A., architect. To-day we give a sheet of details of the upper part of the principal facade which faces the Strand. Next week we hope to publish some further details, illustrative of the first or chief floor of the building.

VENTILATION OF ROOMS, HOUSE-
DRAINS, &c.

MR. P. HINCKES BIRD, F.R.C.S., &c., late medical officer of health to the Fylde Combined Sanitary Authority, has just published a small work on this subject. We have already spoken of Mr. Bird's plan of window ventilation, viz., having a space for entrance of air at the meeting rails and raising the lower sash, blocking up the opening left. The author enters minutely into the subject of room ventilation, and recommends architects and builders to make the bottom beading of windows 2in. to 3in. deep, so as to insure an opening between the meeting rails. The author proposes for an outlet an opening into the kitchen chimney flue under the cornice, and, as far as we can see, practically adopts the Arnett valve, which he condemns as noisy. Messrs. Doulton and Co.'s smoke and air flues are recommended. We are inclined to think an opening 12in. by 6in. is unnecessarily large. A long disquisition on house-drain ventilation followed, in which the author has strung together a number of quotations from sanitary writers, all of which are more or less to the point. Mr. Norman Shaw's open soil-pipe is as usual pooh-poohed, the objections made to it being chiefly those raised in our own pages by correspondents, to which we need not refer here. The author does not appear to know of a similar principle advocated in our pages, but without the liability of the open pipe being choked up; but the objec-

tion urged to open soil-pipes has not been found to exist; in cases we know, in fact, they are more imaginary than real. We quite agree with the other advice of Mr. Bird, that all waste-pipes should discharge outside, and can speak favourably of the form of closet illustrated. This chapter is finished by reference to the model by-laws issued by the Local Government Board, which are quoted in full. The work concludes by a long chapter on the ventilation of sewers, in which the opinions of Dr. F. Letheby, Sir Joseph Bazalgette, Mr. Latham, Mr. Rawlinson, Mr. Ellice-Clarke, and others, are given, and the author adopts the only common-sense view that the freer the escape of air from them the less injurious they will be to health.

BUILDERS' CLERKS' BENEVOLENT
INSTITUTION.

THE twelfth annual general meeting of this institution was held at the offices, 27, Farringdon-street, E.C., on the 25th February, Mr. T. F. Rider, President, in the chair. There were also present, Mr. George Plucknett, Mr. Thomas Robinson, Mr. E. Graystone, Mr. E. Brooks, Mr. J. A. Robson, &c.

The report showed an income for the past year of £297 17s. 11d., and included some liberal donations from the President, the Builders' Society, Mr. E. S. Rider, Mr. Charles Kynoch, and Mr. Edwin Laurence. One additional pensioner, Mrs. Hannah Wade, had been elected, and a second presentation to the Orphan Working School had been purchased, Ethel Mary Jeffreys having been elected to enjoy the benefits afforded by this excellent school. During the year the pensions had been increased to £25 per annum to men, and £20 per annum to widows, and the report concluded with the hope that more of the builders' clerks would become subscribers.

Mr. Rider, in moving the adoption of the report, after referring feelingly to Mr. Colls's death, and to the severe illness of Mr. T. F. Cooke, one of the original promoters of the institution, he said that the year 1878 had certainly been a wretched year. Strikes, war, badness of trade, and calamities, had characterised it, yet, amidst it all, he was happy to say that the institution had held its own, and good work had been done. An additional pensioner had been elected, and another presentation to the Orphan Working School, to which a child had been elected, had been purchased. Again, looking to the balance-sheet, he observed that while the income for 1877 was £292 7s. 10d., that for 1878 was £297 17s. 11d., showing a balance in favour of the latter year. Again, an alteration had been made in the rules, by which the pensions had been increased, and with regard to this latter point he could assure the meeting that the news had been received without any grumbling on the part of the pensioners.

Then, referring to the subscribers, he said he should certainly like to see a greater number of builders' clerks on the list than was the case, and it had occurred to him that if a dinner were held, which he hoped would bring together a good number of clerks, and if they could get gentlemen like Mr. Plucknett, Mr. Robinson, and Mr. Conder to come and encourage them by their presence, he thought it might be a means of making known the benefits offered, and generally be a means of benefitting the institution.

The ordinary business of the meeting was then attended to, and on the motion of Mr. Plucknett, seconded by Mr. Robinson, a vote of thanks was accorded to the chairman, and the proceedings closed.

The Free Library, Bradford, and also the Liberal Club, have been fitted with Messrs. Robt. Boyle & Son's Patent Self-acting Air Pump Ventilators, and we understand the ventilation is pronounced to be most satisfactory.

Mr. Leader Williams, engineer to the Severn Commissioners, died on Wednesday week at his residence at Worcester. He was in his 77th year, and had held his office since 1842, when the Commissioners were established. One of his sons is Mr. Benjamin Leader Williams, the well-known artist; another is engineer of the Bridgewater Canal; and a third is engineer of the harbour of Sydney, New South Wales.

The electric light is being employed nightly upon the Severn Bridge, in directing work during low-water, under the management of Mr. Scholes, the contractor's foreman. It is reported to be a success.

ARCHITECTURAL ASSOCIATION.

At the fortnightly meeting on Friday, the President, Mr. H. L. Florence, in the chair, the following gentlemen were elected as members—J. J. Gaul, J. J. Jones, A. J. Wood, J. R. Duckworth, E. E. May, and H. B. Taylor. It was announced that the next visit would take place on Saturday afternoon, March 8, and would be paid to Mr. J. Oldrid Scott's Greek Church at Bayswater, and to the new Jewish Synagogue near by. The President referred to the death of Mr. Charles J. Adams, of Stockton-on-Tees, who for several years acted as hon. secretary of the Association.

STUDIOS AND MOULDINGS.

Mr. EDWARD W. GODWIN, F.S.A., who had been announced to read a paper upon "Trim-mings," was then invited by the President to address the meeting. He said: Gentlemen, I stand here in a very awkward predicament. I have lost my lecture! (Great laughter). Where, I have not the slightest conception. Up to ten o'clock last night it was safe and written, and between that hour and ten this morning it disappeared. That the lecture was absolutely written I give you my word of honour; your secretary saw part of it, and one of my friends read the peroration. This morning I saw your secretary, and said "I shall back out of it. I have written my lecture as promised, and now it's gone there's an end of it." But Mr. Page said, "No, you are the thing we want, and not the lecture." So as I believe in the Architectural Association immensely, here I am. Well, I am here simply to talk to you about a few studios—I see five sets of my drawings on the walls—that I have lately built. I shall divide my sermon into three heads (I am quite orthodox and regular, you see). 1st, Studios detached; 2nd, Studios in groups; and 3rd, Studios in houses. The architect, like the tailor, should cut his coat according to his cloth: now there are hardworking young artists who have their pictures returned again and again, but who yet want studios built for them—places which shall not display any rare architectural talent. What is wanted is cleverness in designing something cheaper than the builder could manage by himself. At the back of most London gardens there is space for such studios. Thus in the neighbourhood of Gower-street there are stables, which let at from £20 to £30 a year. If the walls on the north side were raised, the south left low, and a lean-to roof or lid from the high to the low wall, with high lights, a working room could be constructed which would cost very little and would easily let to painters at quite £40 or £50 a year. Nothing could be more simple, and nothing more effective. Competition with the builder on his own ground of cheapness is not a bad thing. I tried this some time since at Kensington Palace for the Princess Louise, for whom a builder had volunteered to put up a studio for about £800. The Princess Louise thought this was rather too much for a simple building at the bottom of the garden, and a friend advised her to "go to Mr. Godwin." I built a studio 17ft. high and put over it a kind of Mansard roof, with windows looking into the garden. It is about 25ft. square and has an ante-room attached for the Marquis of Lorne, a little hall, and three entrances. The walls are of red brick, there are green slates on the roof to match the old house, and few would notice that anything had been added to the old building. It is quite as pretty as the builder's would have been. It is admirably suited for a studio, and we managed to put it up for between £600 and £700, including architect's fees. All the light is reflected so as to reduce the horizontal ceiling as much as possible. This studio seems perfectly satisfactory to the Princess, to Mr. Boehm, the sculptor (for it is a sculptor's studio), and also to myself. Now as to lighting a studio, I use a so-called Mansard roof and keep it as steep as I possibly can. The artist is the most extraordinary client that you can deal with—every individual painter has his individual idea as to what a studio should be. One tells me that he wants the light to come straight down from the roof, and another says he must only have a window light, while Pellegrini declares he will have nothing but light—walls and roofs, all must give light. One would be driven mad if he had many painters as clients. Mr. Albert Moore has acted upon the principle of endeavouring to get rid of every right angle, and to reflect as much light as possible.

He has designed his own building—I presume at a much greater cost than if an architect had been called in. The walls and ceilings of this studio are cut about in a most remarkable manner, so that when you go in you think you've got inside one of those many-sided figures used for mathematical demonstrations of angles and prisms. It has, indeed, numerous sides, is very dodgy and well worthy of consideration by every artist. Detached studios may always be built for about £600 or £700 a-piece, and for much less if old walls can be utilised for part of the substructure. Studios thus arranged would be a vast benefit to young painters, most of whom live and work in little rooms of a very inferior character. Frith painted the "Derby Day" in a room which still exists over a French restaurant in Charlotte-street. Whether it would have been a better work had it been executed in a properly-constructed studio I am not prepared to say, but I hope so. Mr. Hamilton Macallum says, "I should like to be in a conservatory when I paint, so as to get plenty of light all round." I fear that if it were anything like the palm-house at Kew he would be half his time trying to shut out and adjust the light. On the wall are a series of

plans and designs relating to a house I have carried out for my old friend Mr. Whistler (applause). He used to paint in one of those ordinary 1st floor rooms looking on the British Museum. Whistler moved to Chelsea, to a very different house in Cheyne Walk, built by Sir Christopher Wren; a small studio with black oak panelling, and looking nearly west with a light somewhat vague and foggy—just the terms in which the Attorney-General was pleased to describe his pictures the other day. I thought he was working under studio disadvantages, and on my suggestion he took two plots of ground in Tite-street, which at the back looked north-east over Chelsea Hospital grounds. My design showed two studios, one 48 feet by 30 feet, the other 30 feet by 20 feet, etching-room, dining-room, breakfast-room, and bedrooms, and was to be built in white bricks and covered with green slates for £1,700. The Metropolitan Board of Works, having let us proceed, at last objected to the design. Of what they said about it in council assembled, things were repeated to me which were positively shocking to one's morality. (Laughter.) They specially objected, I found, to my roof, which was at two different angles. I made a perspective with the utmost care, and I assure you I didn't fudge it one atom, showing that the upper part of the roof sloped at such an angle that the part they objected to would not be visible from the street. They replied that they did not judge by perspective, but by elevation. Could you have believed that any body of men could display such crass ignorance as to think that a building would look, when carried out, like the elevation? There are on wall two designs for Mr. Frank Miles's studio in Tite-street—a most unfortunate name, by the way. It is for a bachelor, is unpretentious, containing about nine rooms, besides studio. The latter is at the top of the house, and is in length the width of two plots—about 40ft. The roof is very steep at base, and then falls off, light being got at the steep slope. The whole house was designed with balconies and other accessories to meet the tastes of a lover of flowers. When the

first elevation was sent to the Board of Works, our respected friend, Mr. Vulliamy, said, "Why, this is worse than Whistler's," that it would be useless to lay it before the Board, and that it would not do, and yet I consider it the best thing I ever did. I grant you there are no cornice, no parapet, and no string-course; but is architecture a matter of string-courses and parapets, and of following out to the letter every detail to which the provisions of the Building Act apply? Because I chose to do something different to the conventional, because I was not in the fashion, and because the Board and its offices knew nothing by experience of the nature of my work, the Board refused to let my design be carried out. Well, I made a second design, as you see, in which I introduced a number of reminiscences of a visit to Holland, and the thing was pronounced charming. This is very sad. I am bold enough to say I am a better judge than the Board of Works as to what is right in architecture. There is no chance for art and originality when such things as that go on at Spring-gardens. It is a disgrace to the whole profession that Spring-gardens exists as it does. And who are they who dare to sit in judgment on my work? What "judgment" have retired furriers and cheesemongers, who never drew a line nor saw a drawing till yesterday? Well, here is another set of drawings of a double house designed for Signor Pellegrini and Mr. Stuart Wortley. In the elevation on the wall that I have submitted to the Board of Works, by talking in a language they have heard of, you will see the house is a double one, with balcony from one studio to the other, and various means of communication, all of which, should it be necessary, can be shut off. Now let me diverge. It has been recently said in this room that there is a certain class of mouldings well suited for use in Greece, and another class that are eminently adapted for England; and the difference between the one and the other has been solemnly illustrated by a gentleman whose attainments are no doubt very great. Now, the class of mouldings which are said to be adapted for Athens, and not for this country, are those we see in the British Museum and in Stuart and Revett; they consist of very fine curves, hardly going beyond a straight line, with a slight turn at the ends, as you see on the blackboard (Fig. 1). In this (Fig. 2) is another Greek moulding, like to the edge of the salvia leaf. These mouldings are of a subtle and delicate character, not to be copied by the use of instruments. Some of these delicate curves I have endeavoured to introduce into my designs, such as this (Fig. 3), and I fail to see that they are not as suitable to England as to Greece. It has been said that our mouldings are bold or coarse because of our foggy climate; but on a wet day one doesn't care whether a moulding has been used or not. I never look at a moulding on a foggy day. When we talk about architecture as a fine art we mean refinement, finesse, gentleness; and these qualities we can always trace in Greek mouldings. At Whistler's house there is an entrance doorway in Portland stone, in which I have endeavoured to express these ideas; you will, it is true, find nothing forceful or bold about them. I do not speak without some knowledge of English mouldings. I have spent hours examining them, with Professor Willis; I have drawn them, measured them, felt round them—when we knew all the time just what we find in them. Here's a typical Gothic moulding (Fig. 4). You may laugh, for there is next to nothing in it. Here (Fig. 5) is a moulding I have used. Had I been a few years younger I should have cut off the lowest member, and notched it. And here (Fig. 6) is a favourite moulding of Mr. Burges's. Most of us understand all about these, but we shall not know all the subtlety that makes the beauty of a Greek moulding till the end of our lives. They are not curves which can be struck with a pair of compasses. The best work of the thirteenth century no doubt approximates in feeling to Greek art. This I have seen in France, and especially at Lisieux some years since. I will conclude by expressing the opinion that earnest studies of the best Gothic work of the thirteenth century will lead us, step by step, back to Greek work. Out of an examination of the principles of working in the best examples of those periods may be evolved in the future something that will

* Mr. Godwin's detail drawings of the apse of Lisieux Cathedral, exhibiting some of these subtle curves, were reproduced in the BUILDING NEWS of Oct. 2nd, 1874.

be more worthy our attention, more refined and finished than either Gothic or Queen Anne. You have seen the church near St. Pancras Station, a copy of a Greek temple. That is not the form in which Greek art is to be revived. The study of the Parthenon will not be much good to you; but in the details of other buildings on the Acropolis, in the Greek colonies, and in the many reliefs and fragments at the British Museum. In these and other examples you will see a refinement and grace which will well repay study, and may be the foundation of the architecture of the future.

Mr. STANNIS proposed a vote of thanks to Mr. Godwin for having said so much of interest in so diffuse a manner. The candid self-criticism with which he had interspersed his descriptions was valuable. The loss of the manuscript might be a source of regret to Mr. Godwin, but they could scarcely sympathise with him, for they had had an address probably quite as instructive, and certainly more amusing, than the lost lecture.

Mr. GILBERT REDGRAVE, in seconding the motion, observed that for some months past Mr. Godwin had excited their curiosity by the wide title of his paper. Since that lecture was irrevocably gone, would he gratify the members by telling them what "Trimnings" were? From the address he had learned that no artist could hope to become great unless he had a studio built for him at the proper time. The "cheap" studio seemed to be a glorified stable; how should such a place be approached?—by the mews or through the house? He did not understand how far Messrs. Pellegrini and Stuart Wortley's formed one or two houses, nor how the requirements of the Building Act were met. Amongst the contrivances for lighting Mr. Godwin had not mentioned the plan adopted by Mr. Cooper, which was an open frieze, admitting light all round.

Mr. RIDDETT inquired as to the best arrangements for screening and warming studios, and Mr. CLARKSON as to the modes of regulating light.

The vote of thanks having been carried by acclamation, Mr. Godwin replied. For the meaning of "Trimnings" he must refer members to his paper. He would explain that some years ago a lady who had lived in Paris said to him satirically of the dress of English ladies, "They import their fashions from Paris, but they exaggerate the trimmings, and the result is vulgarity. What is there a touch of colour, becomes a blotch in London. What was a delicate bow becomes a draggetailed dustcap." He thought the criticism would apply to English architecture as well as English dress, and hence the title of the paper, which he had illustrated with examples from Norman Shaw, Stevenson, Chancellor, and Gundry. If the massing were bad that might be the fault of the client; but if the trimmings were coarse the blame must rest upon the architect. He had been asked as to the entrances to back studios. These might be anywhere, wherever found convenient. One of our lady artists worked in a studio approached by a step ladder—he referred to Miss Wortley. The double house he had referred to was really one with communications on every floor, but they could be separated with the greatest ease. He regarded a studio as at once a workshop, a reception-room, and an exhibition building, and designed it accordingly. For heating he had tried two plans; an open fireplace at one end and an American sun stove or German stove at the other. He preferred the latter form of stove, as it was less drying and retained the heat a long while. As to blinds, tastes differed. Mr. Whistler had white blinds, admirably hung so as to allow no light to come through cracks. Another artist used dark green opaque blinds of some felting substance. He believed Mr. Moore screened his light by hoods over the windows and skylights, and by movable shutters. His own opinion was that when a studio was properly and not over-lighted, no blinds were needed, and that an adjustable shutter at the bottoms of the windows would meet every requirement.

The Hon. and Rev. B. P. Bouverie, rector of Stanton, St. Quinton, whose skill in sculpture is, the *Wiltshire County Mirror* says, well known, is engaged in carving in white marble a full-length recumbent figure of Bishop Hamilton, to be placed on an altar-tomb to the Bishop's memory in Salisbury Cathedral.

The Melksham local board have appointed Mr. J. Hoskins as surveyor.

ROYAL ACADEMY LECTURES ON ARCHITECTURE.

SECOND PERIOD OF RENAISSANCE—BRAMANTE AND SANSOVINO.

THE period of the rebuilding of St. Peter's at Rome, and of the non-Gothic palaces at Venice, formed the subject of Prof. Barry's fifth lecture to the Academy students. A passing notice was made of a contemporary of Brunelleschi, Leon Batista Alberti, who designed some important buildings in the neo-Roman style, including the church of St. Andrew, at Mantua. This edifice is cruciform in plan, but has a semicircular arched roof and crowning dome; the ornamentation is more suited, however, to a secular building than to a church, and the design has the merit of consistency but not that of fitness. It is to be regretted that the Renaissance was based throughout on Roman ideas, and that the beauties of Greek architecture were till long afterwards a sealed book to the Italians. The direct imitation of Roman buildings with all their faults was common, and was notably the case in the rebuilding of the venerable basilica of St. Peter at Rome, a church erected in the age of Constantine, of magnificent dimensions and having a grand internal effect from its double aisles, and their long vista of columns. The Papal Court, however, decided to replace the old basilica by the greatest and most splendid church the world had ever seen, and when Julius II. was raised to the pontifical chair he found the architect for such a design in Bramante, who was born just as Brunelleschi died, and on whom the mantle of the latter seemed to have fallen. Originally a painter, he turned his attention to architecture, and travelled in North Italy, and studied in Rome, acquiring an accurate knowledge of Roman details which no one had hitherto possessed. It is unfortunate that fuller materials do not exist for estimating his talents; for, even at St. Peter's, very little of Bramante's work remains. He was largely employed by Pope Alexander VI., as well as by Julius II., at the Vatican. The Palace of the Cancelleria was partly designed by him, and is remarkable for refinement of detail. There are in it no signs of that worship of bigness which was to triumph at St. Peter's after Bramante's death, but, on the contrary, the parts are small, and perhaps even over-minute. The introduction of pilasters in the two upper stories, a common expedient of Renaissance architects, is open to criticism. Bramante's works were too hastily constructed, and have consequently been largely replaced. In his designs generally, the exuberance of the Early Renaissance became chastened or controlled by a more severe taste, and luxury of detail gave way to a grandeur of style. When summoned by the Pope to advise on the rebuilding of St. Peter's, Bramante submitted a plan of great size and pretension. The arrangement was that of a Latin cross, with five bays of nave arches, and three tribunes for choir and transepts. A dome marked the intersection of nave and transepts. The principal tribune, which is at the west, instead of the eastern end of the church, was erected before the appointment of Bramante, from the designs of Rossellini, by order of Pope Nicholas V. This tribune was retained by all the other architects who were afterwards engaged upon St. Peter's. In his early travels, Bramante had been much impressed by the cathedral at Milan, and the influence of this leaning is to be traced in the plan for St. Peter's, which resembles a northern cathedral in its division into nave, aisles, choir, and transepts. We are left to conjecture his design for the exterior, for at his death, in 1514, the work had not far advanced. Raffaele and Peruzzi followed him as architects, and passed away in rapid succession, after which the work was intrusted to Antonio San Gallo. Michael Angelo spoke in high praise of Bramante's luminous and comprehensive design, but denounced that of San Gallo on the ground of its multiplicity of features, which he said broke it into too many parts, conveying the idea of a Gothic rather than an Antique or Classic building. In this censure we have a key to the artistic feeling of the time. The period of copying had set in, and every building was to be imitated from the antique remains. The five orders became the rule for the future, and the great difficulty of Renaissance architecture has since been in the right use of columns. If they are too few, and large, they injure the scale of the building, as at St. Peter's; if too numerous and small they produce a pettiness of effect, as in San Gallo's design.

It may be concluded that Bramante would not have raised the dome far above the rest of the building, and beautiful as the present dome of St. Peter's may be, it is to be regretted that Bramante had not the opportunity of carrying out his design. The fault of St. Peter's is its great height in proportion to the width, the dome being two and a half diameters high. The time of Bramante has always been considered the best period of the Renaissance, and so occupied the foremost place among the architects of the new faith. His early training as well as his later convictions led him to appreciate beauty of detail, as well as greatness of conception. Although full of Classic feeling, and even prejudices, he yielded but little to the temptation of actual copying, and his designs show an attempt to adapt the style to the requirements of his day, which is the only reasonable justification of a revival. One of the most famous of Bramante's contemporaries was Sansovino, who began palace-building at Venice while Bramante was engaged at Rome in carrying out the Pope's dream of a Christian temple surpassing every ancient or modern building. The Renaissance appears to special advantage in Venice, for Classical precedents were more freely treated there than by other Italian revivalists, and the fusion state lasted longer than it did elsewhere. In the later palaces of Venice Classical details are adopted more extensively and applied less intelligently than in the earlier works, and too many of the façades are more decorated frontispieces. Thus, at the Casa Grimani three orders are employed, but the columns and entablatures seem to be built against the front without forming part of it; the delicacy and finish of the ornaments and the dignity and solidity of the general effect deserve admiration. A better design is the small Palazzo Camerlinghi, near the Rialto, where the pilasters are actual panelled piers, strengthening the wall, and the openings are of Gothic rather than Renaissance proportions. The elevation would gain greatly, however, by a lateral extension. The most important of the Renaissance palaces is the great work of Sansovino, the Library of St. Mark. Placed exactly opposite the Ducal Palace, it challenges a somewhat unequal comparison between the Gothic and the Renaissance. On architectural grounds alone the Library may well hold its own, but the interest men feel in the Ducal Palace is not purely architectural. The effect of the Library, as a whole, is very good. The orders of columns are well proportioned and detailed; and the small window columns in the upper story are skilfully introduced, so as to give scale to the larger order. The proportions of the arches recall Roman precedents, and contrast agreeably with the elongated types used in the Camerlinghi Palace. It is probably owing to the fact that Sansovino was a sculptor as well as an architect, that the profuse ornamentation of the design is due; at the same time the sculpture itself is well designed and executed. The library is certainly one of the best of the Renaissance palaces, although the Roman orders are imitated in it. If that be a defect very few architects of more recent times can afford to throw stones at Sansovino. It may be worth while to consider how far such reproduction of ancient details is of itself an unpardonable defect, and how far it is a special reproach to the Renaissance. Unless we are to have that dream of enthusiasts, an original style, perfect in all its parts, recourse must be had to precedents. We must use the old styles, though we should aim to adapt them to modern use. With the traditional styles, certain details have come to be so intimately associated that the absence of them or their indiscriminate association with other forms, shocks us, like a false quantity in poetry, or a *lapsus lingue* in speech. Any fusion of diverse architectural schools is consequently a task of the greatest difficulty, needing severe restraint, great caution, and abundant knowledge. The architectural student requires to be on his guard in this respect. Too often he is tempted to believe that an indiscriminate hotch-potch of past features is to be the style of the future. Such a mis-use of freedom merits the name of "carelessness," and not that which it claims of "originality." The Renaissance architects have been much censured for the regularity of their designs, but in a compound art like architecture, which demands scientific treatment, the presumption must be, said the lecturer, in favour of regularity in buildings of importance. Although a skilful architect will decline to be

controlled by an absolute symmetrical law, he will remember that symmetry appeals to a natural instinct, and that good reason should exist, if it is to be disregarded in his designs. While the young architectural student ought to study the various forms his art has assumed in the past, he need not copy all he sees. Let him choose his own line and attach himself to whatever school of practice he deliberately prefers. When he has done so he should study it in all its parts and varieties, and he will find that originality springs best from knowledge. The actual forms of architecture obviously do not admit of indefinite variation. The possible curves of an arch or shapes of openings are soon exhausted. These things are as the grammar of our art, or more correctly, the language in which architecture expresses her ideas. As to such matters we need not be afraid of following precedents. None are so clever that they can afford to neglect the stored experience of the world, and when we see some nondescript design we remember the saying that "fools rush in where angels fear to tread." If the architect thinks of the purposes for which his buildings are intended, it is scarcely possible that he can be a literal copyist, while, as to the rest, it is better to copy good details than to invent bad ones. We have seen, in our review of architectural history, that while Gothic art cherished the vertical principle, the Classic architects, and the Renaissance revivalists, adopted horizontalism as their ruling idea. In ornamentation, the conflict has been between the natural and the conventional, not so much in the minor details as in the application of the higher artistic development of sculpture and painting. While men have cherished the old eccentricities of detail in their churches, the artists of the Renaissance went direct to Nature for inspiration. The old Greek worship of beauty became again with them a passion, and their saints recalled the gods and goddesses of old, by their idealisations of human perfections. To the Medieval spirit such ideas were abhorrent. If sculpture could be admitted to the sanctuary, it must be prescribed by conventional religious rules, which ignored the human element. The painter and the sculptor might dwell in an ideal sphere, peopled with saints and martyrs, but a reference to actual facts was forbidden to them. In as far as the Renaissance constituted a protest against such conclusions, it will not be reversed. Our architecture must welcome the best art of its time; and if we expect painters and sculptors to do their best in co-operation with ourselves, we must see that they are afforded free scope for the exercise of their genius. In determining the style of our architecture, such considerations should have weight. We must inquire not only into its special historical and aesthetic merits, but as to its adaptability to modern requirements, not forgetting its flexibility with reference to the assimilation of the sister arts.

SEWAGE POISONING: ITS CAUSES AND CURE.*

THE above is the title of a paper published by Dr. Edward T. Blake, M.R.C.S., read before one of the medical societies. The author observes that the objects of his work are twofold: first, to teach that many diseases which we look upon as unavoidable are really the reverse; and second, how we may defeat the twin demons—Ignorance and Indolence. Dr. Blake observes truly enough that there are certain conditions necessary to predispose us to the diphtheritic virus. In the case of children, it is necessary that the vitality must be lowered by exposure to sewage infection or some debilitating agency; that there must be actual loss of surface in the throat; and lastly, the presence of the diphtheritic germ. Again, he says the throat may be denuded, and prepared for an attack by catarrh, which latter corrodes the "mucosa" of the pharynx. We may observe, in short, that the author indicates the true explanation why some persons escape and others fall victims to these diseases, and he points out clearly their connection with the sanitary defects of our houses. The engravings which illustrate Dr. Blake's pamphlet show various typical arrangements, such as vastes acting as ventilators and cisterns saturated with sewer gas. Next the reader

is shown how these defects can be remedied, and the best made of a bad system, by disconnection of house-drains with sewer, and by air-shafts carried up on both sides of the house-drain, so that currents may be established in the system outside house. Among the evils of untrapped wastes are mentioned sinks, lavatory and bath wastes, the habit of turning the waste-pipe which drains tray under closet into the soil-pipe, &c., instead of letting it discharge outside. The author recommends soil-pipes to be placed outside the walls of houses, no metal being employed, and carried up above roof, in addition to a ventilating shaft leading from an inspection shaft on the sewer side of siphon, by which the gas passes up or down. Another diagram shows the connection of stack pipes. To continuous stack pipes communicating directly with house-drains and terminating above the window-heads, as in ordinary London houses, the author attributes immunity from disease, but he suggests that they should discharge over open gully traps. In short, Dr. Blake recommends the doing away with waste-pipes, or allowing them to discharge above gully gratings; ventilating soil-pipes, the removal of lids to j.w.c.'s D-traps; the abolition of cisterns for drinking purposes above closets, and the use of slate, or glazed stoneware instead of lead for the latter, open both to light and air. A dry area round every house is also recommended.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

GLASGOW INSTITUTE OF ARCHITECTS.—A meeting of this institute was held on Feb. 27; Mr. Campbell Douglas, the president, in the chair. The secretary then read the correspondence which had taken place between the council of the institute and Town Council of Greenock regarding the terms of the proposed competition for the new Municipal Buildings. The president said that while it was to be regretted that the Greenock authorities had disregarded their remonstrances, and refused to alter the stipulation limiting the rate of remuneration to 4 per cent., he did not think that the action taken by the institute laid any obligation upon its individual members to refrain from engaging in the competition. They by no means advocated uniformity of payment irrespective of circumstances.

COMPETITIONS.

CASTLEISLAND.—Out of several designs sent in for a new R. C. Church, Castleisland, Co. Kerry, Ireland, the designs of Mr. D. C. Coakley have been selected. The church is to cost £8,000.

SPALDING.—Drawings submitted in competition for the new Johnson Hospital at Spalding will be on view to-morrow at the Sessions House, Spalding. The cost of the building is not to exceed £4,000, and accommodation is to be provided for twenty patients and the official staff, and to include a semi-detached public dispensary. A premium of £50 has been offered for the best design. The conditions seem carefully drawn, and competitors for similar works may note the fact that architects are advised to read an article on Hospitals by J. R. Martin, pp. 1006–1063, in Vol. V. of "A System of Surgery," edited by Holmes (London: Longmans, Green and Co., 1871), and Machinell's Ventilation, p. 1025.

SCHOOLS OF ART.

MANCHESTER.—The annual meeting of the Manchester School of Art took place on Wednesday week. The annual report stated that the school had this year obtained 2 silver medals, 3 bronze medals, 4 Queen's prizes, 17 third-grade prizes, and 1 second grade prize. At the second-grade examination in May last, 17 students gained "excellent" and 29 "passed." A third-grade advanced examination to be held annually at provincial art schools had lately been instituted by the Science and Art department. Last year an examination was held in Manchester, when five of their students presented themselves. One obtained "good," and three "passed."

A paper was read on Tuesday evening, the 25th ultimo, before the Manchester Architectural Association by Mr. Charles Luke upon the subject of pneumatic sewerage. It was illustrated very plentifully with plans and details of the two systems invented by Captain Liernur and Mr. Isaac Shaw, C.E., respectively.

Building Intelligence.

ROTHERHAM.—On Saturday afternoon the first Board Schools which have been erected by the Rotherham School Board were opened. They are situated at Thornhill, and are built in the Late Gothic style from designs which have been prepared by Messrs. Tacon and Rawson, of Rotherham, who were appointed architects to the Board by competition. The schools are built of red pressed bricks with stone dressings, intermixed with ornamental terra-cotta work. The girls' and infants' entrance, which is carried up as a centre feature, is surmounted by a tower and bell turret. Each school has two classrooms, and altogether accommodation is provided for 700 children. The works have been carried out by Mr. Charles Ripley, of Rotherham, the contractor.

METROPOLITAN BOARD OF WORKS.—At this Board on Friday, the Works Committee brought up a report with reference to the whole question of the expediency of extending the tramway system in the metropolis, and especially the particular Parliamentary schemes of the present year. They recommended (a) That the Board do not consent to the construction of any line of tramway in any road or street within the Metropolis where the requirements prescribed by the statute regulating the distance between the kerb and the tram line have not been complied with; except where passing places are required in the case of single lines of tramway, or where there are special local circumstances requiring a modification of the rule. Subject to clauses inserted in the Bills, providing that the general Companies shall adopt with all reasonable despatch any requirements made by the Board of Trade, for such improvements in the tramways and their rails, as experience may from time to time suggest. Consent was given to the construction of the following lines of tramway, all others being refused:—North London Tramways—in Stamford-hill, between Bayley's-lane and Upper Clapton-road. South London Tramways schemes, viz.,—Wycliffe-grove, along Lavender-hill and Wandsworth-road to Nine Elms-lane; from that lane along Wandsworth-road and High-street, Lambeth to near Vauxhall-walk; and from this walk along High-street, the Albert-embankment, Palace-road, York-road, Stamford-street, and Southwark-street to High-street, Borough. London Tramways schemes, viz.,—along Borough-road from St. George's-circus to Newington-causeway; from Old Kent-road along Bermondsey-new-road, Grange-road, and Blue Anchor-road to Jamaica-level; from Raymouth-road, along Jamaica-level and Union-road to Deptford Lower-road; from Union-road along Deptford Lower-road to Rotherhithe New-road; from Jamaica-level, along Raymouth-road and Rotherhithe New-road to Deptford Lower-road; from Rotherhithe New-road, along Deptford Lower-road and Evelyn-street to High-street, Deptford; from Water-lane, Brixton, along Brixton-rise, Brixton-hill, and Streatham-hill to St. Leonard's Church, Streatham; and Waterloo-road from St. George's-circus to within 100 yards of the Surrey abutment of Waterloo-bridge (but not over that bridge). London Tramways scheme:—from Kentish-town-road, along Prince of Wales-road, Malden-road and Southampton-road to Circus-road. It was resolved to oppose the West Kent Main Sewerage Bill. Applications from the Fulham District Board for permission to borrow sums of £9,500 for sewerage, paving, and other works, and £7,700 for the formation of roadways and for asphalt pavings, were granted.

As many persons have interested themselves in the preservation of Wren's church at St. Mary-at-Hill, the destruction of which is threatened by the Metropolitan and Metropolitan District for the completion of the Inner Circle, it will be satisfactory to them to learn that the railway companies have agreed to insert a clause in the Bill which will insure the complete preservation of both church and churchyard.

The new church at St. Fillans, N.B., was opened on Sunday week. The church has been built in conformity with plans furnished by the architect to Lady Willoughby, who is evidently of an eclectic turn of mind, the style being described as "a mixture of Gothic, Dutch, and Flemish."

The Guardians of Marylebone accepted on Friday week the tender of Mr. Baker, of Lambeth, amounting to £109,348, for the erection of a new infirmary at Notting-hill.

* Sewage Poisoning: its Causes and Cure. By EDWARD T. BLAKE, M.D., M.R.C.S. London: Hardwicke and Bogue.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 21d. Office: 31, Tavistock street, Covent-garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 33s. 40s. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30s.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—R. C.—J. J.—P. and S.—J. W. S.—G. R.—T. C. H.—H. B.—R. and E.—R. C.

R. W. B. (Write the Secretary at Burlington House.)—C. F. W. (Rather beyond our province. We have inserted the query in the *English Mechanic*, wherein it will appear, and will probably be replied to.)

PHIPPS.—(The treatise on "Masonry" in Weale's series, and another published by Messrs. Cassell on "Tracery" in their technical handbooks, will be found useful.)

PER ARDUA.—(If the plans are tinted yellow, the sectional part should also be tinted that colour, though red is the proper tint for brick walls, both in plan and section.)

"BUILDING NEWS" DESIGNING CLUB.

DESVICH. (There is, as you found out, a resemblance between "Mechlin's" design we published last week, and the Swan Inn, Llanmilling, but not greater than we have seen before between works of architects of repute. It is impossible for us to become detectives in every case of this kind, and if some architects are found dishonest enough to "crib" from others' designs, can we wonder at the infection spreading?—"Triangle in Circle," (sent.)

DRAWINGS RECEIVED.—"Ubique," "Cymraeg, J. G. in squared circle, Pat Norwich, Through and Dagger.

Correspondence.

NEW PREMISES OF THE ART UNION OF LONDON.—EXTORTIONATE CHARGES.

To the Editor of the BUILDING NEWS.

SIR,—The Art Union Society's Offices illustration in last week's BUILDING NEWS is good in parts, and has a generally pleasing effect in execution. Because it has such merit, one cannot but be surprised by the perverse eccentricity which it manifests. General precedent and common-sense notions of propriety dictate that the more massive part of the design should be below, the building getting lighter and more ornamental in treatment towards the top. In this design such rule is reversed, the most massive story being the upper one! The three stories (each good in themselves) want transposition: the upper one to come to the bottom; the bottom one to the first floor; and the ornate and elegant first floor treatment to the top. Of course, this only strictly refers to the character of each floor; if so transposed some alteration would be involved. The objectionable heaviness of the upper floor is further augmented by the solid attic over it, which is in harsh contrast to the light balustrades on lower floors. What a

pity the roof was not hipped, and an open balustrade put also on the top.

Allow me to say a word on another subject, which may be a useful hint to many. I lately sent an advertisement to the BUILDING NEWS, as also to another architectural paper. From the latter came a demand for 10s. 6d., to be paid in advance. I was too busy to attend to it, and supposed it would really make no difference. The advertisement, however, did not appear. It duly was published in the BUILDING NEWS, and the charge, I find, is 4s. 6d. —I am, &c.,

M.

COLOUR IN ARCHITECTURE.

SIR,—I have read with some surprise your report of a paper by Mr. W. Tonks read before the Birmingham Architectural Association. Mr. Tonks tells us that "the polished surfaces of granites and coloured marbles are but slightly affected by the atmosphere." Now this is dangerously misleading. The polished surfaces of granites may stand, but Mr. Tonks can find no example in England where the polished surfaces of coloured marbles have stood exposure to the weather for more than a few months. When he is next in London let him look at the fountain at the corner of George-street, Westminster; it will probably satisfy him upon this point. Farther on he remarks, "the use of terra-cotta of different colours is now common on the Continent, though but little adopted in this country." In what Sleepy Hollow can he have been reposing? Will he kindly tell us any modern public building on the Continent where terra-cotta has been used to such an extent, and with as much success, as in the new Natural History Museum at Kensington? If he were a constant reader of your paper he would find that he has made an altogether erroneous calculation of the amount of this material used by English architects. In speaking of things at home he is still more inaccurate. He tells us that terra-cotta has been used with good effect upon "the Grand Hotel" and the "School Board offices." As a matter of fact there is not an inch of terra-cotta upon the Grand Hotel, and no such building as the School Board offices exists. Indeed, it was only a few days ago that a member of the Board claimed for that body the merit of almost Spartan virtue because they had spent none of the public money in building a house for themselves; that, while the Town Council were seated on velvet, the members of the Board were content with wooden chairs—board to board in fact. I would not trouble you with this, only that I am of opinion that two things are absolutely necessary for a lecturer: firstly, that he himself should understand something of the subject he is talking about; secondly, that his statements, to be of any value, should be correct.—I am, &c.,

A BIRMINGHAM READER.

DISTRICT SURVEYOR'S FEES.

SIR,—A decision, given by Mr. Newton on Tuesday last at the Marlborough-street Police-court, in the case of Kerr v. Adams and Son, appears to me of so much importance to architects and their clients, as well as to contractors, that I should be glad if you would allow me to draw the attention of your readers to the facts of the case. I have recently been engaged in designing and superintending some extensive alterations at the Army and Navy Club, the building contract for which was let to Messrs. Thos. Wontner Smith and Son, with the usual clause that they should give notices and pay the district surveyor's fees. Notice was duly given by them, in which some of the structural alterations were named, and *etc., etc.*, placed after them to cover the rest. During the progress of the works, various firms were employed by the Committee to put in sundry fittings—amongst others, Messrs. Adams and Son, the well-known engineers of Marlborough Works and the Haymarket, who contracted to put in some new hot-closets, with the necessary steam-pipes, *etc.* Mr. Kerr, on hearing that this was being done, summoned them for not giving him notice, and also for placing a steam-pipe within less than six inches of any combustible material; the penalty in each case being £20; although he had never previously communicated with them or given them any notice to alter the pipe, which, by the way, was fixed in error and altered before the summons was delivered. Mr. Newton ruled that he was entitled to a notice from Messrs. Adams and Son, as the steam-pipe was not mentioned in the

notice given by Messrs. Smith and Son to the builders. Now, the question arises, if the district surveyor is entitled to a notice from every contractor employed, will he be entitled to a fee from each?

In a large building like this I venture to think this is a serious question. One other contractor, employed to put in an additional boiler, did, I am informed, give notice, and others are perhaps liable to be summoned for not doing so, thus there may be some five or six large fees charged on the same building for works all going on at the same time, and to which the district surveyor has made just one visit of inspection, as Mr. Kerr admitted to be the case, though he stated he had sent a clerk at other times. If I am right in assuming that all who give notice will be severally liable to pay the fees, it will be necessary, where several contractors are employed, to see that one gives notice for all, and in doing so to see that every item of the works is specifically given in the notice; no easy matter in works of such a character as the one now in question.—I am, &c.,

HUGH ROUMIEU GOUGH.

ARTISTIC BLOWER TO OPEN FIRE-PLACES.

SIR,—Has not Mr. Edward Starr, who wrote to you on this subject last week, rather missed the artistic value of the iron bar at the bottom edge of the glass blower? He says the bar "makes an unsightly line across the fire-opening," and adds that he considers a shaped and ground edge an improvement. In my opinion glass treated in this way would be open to considerable objection, and that the iron or brass frame is not only a constructive advantage, but an artistic necessity.—I am, &c.,

AN OLD TEE SQUARE.

R.S.A. EXHIBITION.

SIR,—An "A.R.I.B.A." should know that two blacks do not make a white; that, whether his church or spire were the after-thought, the scale of either is too large. At least, that seems to be the reason why the effect is not artistic. A large scale reduces the space available for surroundings, which help to gauge the proportions of an edifice, and help, also, the making of a picture. But this is not the head and front of its offending. It creates larger blank surfaces, which must be all etched over. When this is not done with taste, the expressive lines are lost or impaired in their effect by the coarse surface lines, which express nothing of design at all. The light and shade is lost, and the result is general confusion—whatever its effect may be upon a building committee looking out for something big.

The notice mentioned by Mr. Fairley refers exclusively to oil-paintings and broad gilt frames. Mr. Fairley's design would not only have been admitted by the hanging Committee, but it would have done more justice to itself—had the frame been as it is and the picture less. It is not so much the size as the shape of the drawings which makes the packing present arrangements, which look as if a little consideration could have made them better. The task of hanging the oils is a heavy one, compared with which the arrangement of architectural sketches is a trifle. With a few exceptions in respect of the principal positions, the work is probably left to the discretion of the journeyman joiner, as being beneath the artist's notice, or probably beyond his criticism.

In the matter of towers and spires, and picturesque embellishment of church design—the following notice of a church, built by Lady Willoughby, at St. Fillans, on Loch Earn, and opened recently, appears in the local print:—"The church is seated for 250, and is an exceedingly neat, commodious, airy, and well-lighted edifice. The style of architecture is a mixture of Gothic, Dutch, and Flemish, and the little church, with its bulbous tower, relieved by the dark, rugged hills behind, forms an object of beauty in the landscape." If the Highlander is not so consistent as Mr. Shaw, he is, at least, more cosmopolitan in his taste.—I am, &c.,

R. S. ACADEMY.

SIR,—Whatever your correspondent, "R. S. Academy" may have intended in his remark "inevitable tower and spire," and its relation to the rest of his critique, I have merely to consider the statement as it appeared in your columns, where it is distinctly and exclusively part of a sentence referring to a special design. It is, to say the least, somewhat disingenuous of your correspondent to represent it as having any other implication. He surely has not seen his communication in print. Allow me to repeat his words: "A U. P. Church in Dundee is a water-colour sketch of a design in the

Norman or Romanesque, and comprises nave and transepts, with the inevitable tower and spire at the corner."

I am quite aware that the general principle, as your correspondent expresses it, is of more consequence than the details of the design referred to; but I also know that when any special design is commented upon in connection with inaccuracy of analysis, it is neither creditable to the critic, nor just to the design criticised.

It may satisfy your correspondent to justify his use of the term "spire" by reference to popular opinion thereon, but he might have remembered that professional readers have a preference for technical accuracy.—I am, &c.,

Dundee.

G. S. AITKEN.

*** We can insert no more letters on this matter.

Intercommunication.

QUESTIONS.

[5699].—**Driving Sewer Headings.**—I should be obliged to any correspondent who would give me a description of the plan pursued in laying drain-pipes, and constructing brick sewers in tunnel; with the method of timbering, the removal of excavation from the heading; the distance apart necessary for shafts, manholes, &c. I.—Rushton.

[5700].—**Bricks.**—"Student," in thanking Mr. Ambrose and "J.S." for so thoroughly clearing up the girder question, wishes to ask where he might find some information about bricks, as to different kinds and qualities, and how to distinguish one from another. For instance, how to know kiln-burnt from clamp-burnt; hand made from machine made, and good qualities from bad.—STOENT.

REPLIES.

[5652].—**Casts of Carving.**—"Harry Hems" is as impatient at being corrected as a spoiled baby. He stated that pipe-clay was found principally near Chudleigh. Now, as some of your readers seeking further information might, on the strength of such a statement, proceed through Newton Abbot to Chudleigh, a distance of six miles, only to find that they must return to the former place again for what they required, I thought it a pity that people should be so misled, and without the slightest animus against "Harry Hems," who is an utter stranger to me, I remarked in your next issue that the clay was found in the neighbourhood of Newton Abbot, and that the merchants had their places of business in that town and the neighbouring village of Kingsteignton. For making this kindly-meant correction, "Harry Hems" says I am "censorious." The following corrections of "Harry Hems's" statements in your last number are reliable:—Newton Abbot has a population of nearly 10,000, and is the market and business town of the important district which includes all the chief watering-places of South Devon. Chudleigh is a small inland town with a population of less than 2,000, and has been void of animation ever since the coaching days, which preceded the railway era. The pipe and potter's clays are found in the parishes of Kingsteignton, Newton Abbot (Wolborough and Highweek), Henneck, Teignrace, and Bovey Tracey. The clays are the result of decomposed granite, and give employment to a considerably larger number of hands than the 200 named by "Harry Hems." Between 50,000 and 60,000 tons of these clays are taken down the river during the year to be shipped at Teignmouth, and large quantities are forwarded by rail to Dartmouth, for the same purpose. Messrs. Watts, Blake, Bearn and Co. have works for china clay of a very different material to the clays mentioned above, at Cornwood and St. Austell, but their office is situated only at Newton Abbot. Messrs. Brown, Goddard and Hatherley's office is at Kingsteignton. This is the oldest firm in the trade. The Devon and Courtenay Clay Co.'s office is at Newton Abbot. The Devon and Somerset Clay Co. (Limited), has its offices in London. The last-named Co. is a small one, and has recently commenced business. The latest published return of the shipping dues of the different companies at Teignmouth is dated July, 1877. According to it, Messrs. Watts, Blake, Bearn and Co. paid £211 6s. 8d.; Messrs. Brown, Goddard and Hatherley, £113 5s. 10d.; Messrs. Whiteway and Mortimer, £86 19s. 5d.; and the Devon and Courtenay Clay Co., £82 18s. 11d.—J. B.

[5674].—**Ordinance Datum.**—In the "Abstract of the Principal Lines of Spirit Levelling in England and Wales," by Colonel Sir H. James, published by order of the Secretary of State for War, and sold by Longman and Co., there are thousands of recorded heights above Ordnance Datum over the whole of England, along the lines of levelling, and very probably the marks will be referred to which "Beta" requires. The "Datum Level" for Great Britain is the level of mean tide at Liverpool from observations of the Ordnance Surveyors, which is eight-tenths of an inch above the mean tidal level as shown by the self-registering tide gauge on St. George's pier at Liverpool.—M. V. and M.

[5692].—**Girders.**—"Student" does not state, in his question, the whole of his case. The rule he quotes from Tredgold is for the deflection of beams, while that which he quotes from "Hurst's Handbook" is for the strength—that is for the breaking strength. Both are correct when properly applied.—C. S.

[5694].—**A Young Architect's Library.**—It is impossible to give a list of books that shall suit all students, much less casual readers. I will, however, give a list of works under each of the heads suggested, that will be found reliable. 1. Mathematics: Todhunter's "Geometry for Beginners," the same author's "Trigonometry;" Tarn's "Geometry for Architects;" Gregory's "Mathematics for Practical Men." Surveying: As an elementary

book T. Baker's "Mensuration and Land Surveying," in Lockwood's series; Simons on "Levelling." For measuring and valuing, Dobson and Tarn's "Student's Guide," is perhaps the best, though there are many other elementary works that may be named. Ryde's "Text Book." Under Construction, &c., I would recommend as elementary works, the treatises in Weale's series. Tarn's "Science of Building," Fenwick's "Mechanics of Construction," Rankine's "Applied Mechanics," Prof. Moseley's "Mechanical Principles of Architecture," Tredgold's "Carpentry," Fairbairn's "Application of Iron to Building," Barlow on "The Strength of Materials," Stoney's "Theory of Strains," Hatfield's "Transverse Strains," "Treatise on Construction," in "Encyc. Brit.," also "Architectural Dictionary," Burnell on "Limes, Cements," and Reid on "Portland Cement." Donaldson's "Specifications." The Vols. of Building News. Laxton's "Examples of Building Construction." Robinson's "Domestic Architecture," Wightwick's "Hints to Young Architects," Guillaume's edition. Under purely Architectural and Ornamental works, I would name the following, though the list may be largely extended in this branch. Fergusson's Handbook, his "Hist. Principles of Beauty"; Parker's Glossary; Stuart and Revett's "Antiquities of Athens"; Wilkin's "Roman Architecture"; R. Wood's Works; Sharpe's "Architectural Parallels, Seven Periods"; Ruskin's "Seven Lamps"; Scott's "Lectures on Medieval Architecture"; Paley's "Mouldings"; Pugin's "Principles and Specimens"; Shaw's "Specimens of Elizabethan"; Johnson's "Architectural Sketches in France"; Nesfield's "Specimens of Medieval Architecture"; Dalhousie's "Examples of Domestic Architecture"; Parker's ditto; J. B. Waring's "Illustrations of Architecture and Ornament"; Owen Jones' "Grammar of Ornament"; Viollet le Duc's "Dictionary"; Gwilt's "Encyclopædia"; Audsley's "Dictionary of Architecture," &c. Works on ornament, and examples of old buildings in various styles are too numerous to mention, but the above works still form a good nucleus, and are all reliable and standard works.—G. H. C.

[5695].—**Measuring Plaster Work.**—Walls to be measured from top of grounds to half-way up cornice. All openings above 6' 0" super. to be deducted.—B.

[5695].—**Measuring Plaster Work.**—When plasterers find materials, deductions must always be made for doors, windows and fireplaces, and the returns at the tops and sides of doors and windows must be measured separately; but for workmanship only, these deductions are generally omitted, the plastered returns being allowed to counterbalance them. Deductions are never made for cornices, enriched mouldings, festoons, or other ornaments; because the spaces occupied by them are invariably plastered previously to such ornaments being made. If cornices do not exceed 9 inches in girth, they are rated at so much per foot, lineal measure; but all above this girth are computed by the square foot.—W. C. SHADDOCK, Plymouth.

[5695].—**Measuring Plaster Work.**—Rendering to walls is measured by taking the length by the height, the latter being taken from the top of the skirting grounds to the ceiling, and where there is a cornice it is customary to deduct from this dimension half the height of the cornice. Lathing and plastering to partitions is measured in a similar manner, with the exception that where cornices occur it is customary to deduct only one-third the depth of cornice from the height, instead of one-half as described to walls. In case of deductions for doors and windows, take the full dimensions for length and height to the outside of grounds, and not the net dimensions. In the case of doors the height, where there is a skirting, must be taken from the top of the skirting grounds, and not from the floor, so by deducting the full measurements of all openings that occur from the superficial area, the net dimensions of the plasterers' work is obtained, which is the usual way of measuring it. The hollow behind the skirting boards harbours vermin, and the plastering is sometimes continued down to the floor so as to fill it up; when such is the case, a superficial area should be taken of that and describe as rough-plastering behind skirting boards. You will see by the above that the small window you mention in your question, 3 feet x 3 feet = 1 yard super., will have to be deducted from the area to obtain the net dimensions.—ANTHONY WATSON.

[5695].—**Measuring Plaster Work.**—If you form the quoins of the openings or strike a quirk round a bead, unless paid extra for the same, you can measure the whole opening. If you plaster behind the skirting you can measure from floor to ceiling, otherwise you can't.—W. S. TIPPERT.

[5696].—**Brick Wall.**—Tie the two portions of the wall together every fourth course with iron ties about 2 feet 6 inches apart; 1 inch x 1/2 inch opened at the ends dipped in hot tar.—G. B.

[5696].—**Brick Wall.**—The cavity "C. C. C." means must be a 2 1/2 inch one, not 1 1/2 as printed. The method of tying the 9-inch wall to the 4 1/2-inch wall is simple enough. Wrought-iron cramps, dipped in tar, or of galvanised iron, are the best to use; these are strips of flat bar iron, about 8 or 9 inches long, and about 1 inch wide, forked at ends by a slit in middle. In the centre the bar is bent, so as to prevent the lodgment of mortar droppings. These cramps ought to be placed, say in every fourth or fifth course, and about 2 feet 6 inches apart. They are best set in cement, though common mortar is generally used. The positions of the cramps should alternate with one another in the different courses, so as to secure a uniform tie. The principal caution to be used is that the mortar droppings should be carefully removed from them as the work advances, so that there should be no connection between the outer and inner walls.—G. H. G.

[5696].—**Brick Wall.**—The best way to tie a hollow brick wall is with some pieces of flat iron. It must first be heated, and a twist be made in the middle, to keep it from conducting the water.—W. S. TIPPERT. St. Columb.

[5696].—**Brick Wall.**—Hollow walls, such as "C. C. C." describes, generally have wrought-iron ties across the cavity. These ties should have the ends split or "caulked," so that they may be well bedded into the brickwork. If the portion in the cavity is bent a little in the shape of a U, it will prevent any water passing from one side of the brickwork to the other.—R. J.

[5696].—**Brick Wall.**—A 16-inch hollow brick wall.—It is best to have the 4 1/2-inch portion at the outside, and the 9-inch in the inside, leaving the cavity of 2 1/2

inches, instead of 1 1/2, as stated in your question. The advantages of the thin portion outside is, 1st, That the damp is at once intercepted by the air space, keeping out of the greater portion of the wall, and at a considerable distance from the interior of the building. 2nd, The roof can be economically arranged so as to rest upon the interior thicker portion of the wall. Ties of wrought iron are better than bonding bricks, and have the advantage of not being liable to be broken if the wall should settle unevenly. They are generally about 8 inches long, 1/2-inch wide, by 1-10-inch thick; they are placed about 3 feet apart horizontally, and with 9-inch or 3 courses of bricks vertical intervals between the rows. Each tie is either bent in the middle, or twisted to stop the passage of water along its surface, or as to stop the centre, so as to answer the same purpose, and to give them strength to resist compression. The ends are split longitudinally and corked or caulked, i.e., turned in opposite directions, right and left, so as to have a better hold of the brickwork.—ANTHONY WATSON.

[5697].—**Weight of Wrought Iron Girder.**—The weight of a riveted plate girder, as given in Mr. Banister Fletcher's book on "Quantities," Fig. 38, p. 92, worked out at 40lb. to the foot superficial of 1 inch comes to 16cwt. 2qr. 2lb. exclusive of rivets; the rivets come to 3qrs. 14lb. Total, 17cwt. 1qr. 16lb.—ANTHONY WATSON.

[5697].—**Weight of Wrought Iron Girder.**—The weight, viz., 12cwt. 1qr. 25lb. is a misprint; it should be 17cwt. 2qr. 0lb. This error was evidently not discovered until after the second edition of Mr. B. Fletcher's valuable work was published, when it was corrected. Independent of rivets I make the weight 16cwt. 1qr. 27lb. 6/360 = No. 360 of 2 1/2" x 3/4" rivets = 1cwt. 1qr. 0lb. Total, 17cwt. 2qr. 27lb. The difference, viz., 27lb., may arise from the different methods of calculation; or, perhaps, I may, with "Learner," not rightly understand the item for rivets; yet, by taking the rivets as 3/4" diameter, I make the total 7lb. more still. The following alterations appear in the second edition of the items referred to by "Wm. W.," but the others remain the same:—5th Item 2, 3.10; 9, sunk work, (top); 10th, 1 nitre; 11th, 500; 6, egg and tongue carving; Last, 2 narrow circular, &c. As to measurement, I hope to see some explanation by Mr. B. Fletcher, or one of your many readers.—BROTHER LEARNER.

[5697].—**Weight of Wrought Iron Girder.**—I also am not in the possession of sufficient "ingenuity" to work out the weight of Mr. Banister Fletcher's girder so as to make it 12cwt. 1qr. 25lb. "Learner" will see that there are 60 rivets in each row, and as there are 6 rows of rivets 2 1/2 in. long we get 75ft. of metal pin in diameter. The following is what I make the weight of the girder to be:—

20'0	16 = 30'0 in. web	= 7'6 one inch thick.
20'0	9 = 15'0 in. bottom flange	= 7'6 " " "
20'0	9 = 15'0 in. top do.	= 11'3 " " "
4) 20'0	8 = 53'4 in. angle irons	= 20'0 " " "
		46'3

6) 60'2 in. by 1/2 in. rivets.
6 x 60 x 2 1/2 in. = 75ft. x 1/47lb. (the weight of 1ft.) = 110'25lb. in the rivets. 46'3 x 40 (the weight of one superficial foot of metal in. thick) = 1850lb. Thus in the whole girder we have 190'0'25lb., or 17cwt. 2qrs. 0lb. With regard to taking the rivets, it is not generally the practice to add 5 per cent. on to the weight of the web, flanges, angle iron, &c.—R. J.

STAINED GLASS.

ST. EDWARD'S CHURCH, CAMBRIDGE.—The east window of this church has been filled with stained glass by Messrs. John Hardman and Co. It is of the Decorated or fourteenth century period, and consists of five lights and tracery. It has been treated with rich canopy work, and each light contains two subjects, the upper one being the more important. The five main subjects are: The Adoration of the Magi, Baptism of Our Lord, Crucifixion, Angel Appearing to the Holy Women at the Sepulchre, and Supper at Emmaus. The smaller groups beneath are: The Angel Pointing out the Star to the Magi, St. John Pointing out Our Lord, "Ecce Agnus Dei," the Carriage of the Cross, St. Mary Magdalene Sitting at the Tomb, and the Journey to Emmaus. A handsome brass plate, also by Messrs. John Hardman and Co., is placed beneath the window, and records the intention of the donor.

TEDDINGTON.—Six stained glass memorial windows have just been placed in the Church of SS. Peter and Paul, Teddington, Middlesex,—four in the south, and two in the north aisle. The windows are single light ones, and contain, respectively, the figures of St. Peter, St. Andrew, St. James, St. John, St. Paul, and St. Jude. The work has been carried out by Messrs. Powell Bros., of Leeds (whose agents in London are Messrs. Chubb and Son, of St. Paul's Churchyard), the designs having been previously submitted for approval to Mr. G. E. Street, R.A. Messrs. Chubb have also supplied eight coloured windows by the same makers for a gentleman's house in South America. The windows are square, and are to be set in the panels of doors, the centre pieces being elaborately-executed figures of the seasons, &c.

The death is announced of Mr. John Cotterall, builder and contractor, of Blackburn, at the age of 41. Amongst the contracts he carried out was the free library, St. Joseph's Catholic chapel, Harwood-street Wesleyan chapel, the new cattle market, and many other important works. He was a member of the Town Council.

LEGAL INTELLIGENCE:

DANGEROUS HOUSES.—At Marlborough-street on Friday last, Mr. Napier, on the part of the Metropolitan Board of Works, applied to Mr. Mansfield under the Building Act, 15 and 19 Vic., cap. 122, section 80, for an order for the removal of the inmates of the houses, 17, King-street, and 74, Cross-street, those houses having been certified by Mr. Kerr, the district surveyor, to be in a dangerous state. Orders had been already made at that court, but had not been carried out. Although the application was an *ex parte* one under the Act, yet out of courtesy to Mr. Fletcher notice had been given to him that an application was to be made so far as regarded 17, King-street. Mr. Kerr gave evidence to the effect that the house was in a most dilapidated state and might fall at any moment, and also that the order of the Court had not been obeyed. A person asked for an adjournment on behalf of Mr. Fletcher. Mr. Mansfield said that after what had been stated by the surveyor he should make an order.

Our Office Table.

DURING the past two months many additions have been made to the Parkes Museum of Hygiene, and it is expected the museum will be opened to the public before the end of April. The additions to the contents include drawings of the Peabody-buildings for the Poor, presented by the architect, and a number of designs for cottages, villas, &c., by Mr. Norman Shaw, R.A. The collection of sanitary appliances now includes several patents by Messrs Tonks and Son, of Birmingham. The library now has in it upwards of 400 volumes, exclusive of pamphlets. Pending the opening of the museum to the public, tickets of admission may be had on written application to the curator, Mr. Mark H. Judge, University College, Gower-street.

MR. OGLE TARBOTTON, F.G.S., the borough engineer of Nottingham, has just published a pamphlet on the Meteorology of that town—the result of observations conducted by him during the last 12 years. The diurnal observations are made at 9 a.m., and the instruments employed are those of Messrs. Negretti and Zambra, and Mr. Casella, of London. The barometers are corrected by James Glaisher, Esq., at the Royal Observatory, Greenwich, and the thermometric readings are taken 4ft. above the ground on shade and on the grass; those in the sun are taken with a blackened bulb in vacuo. Rainfall is gauged on the ground, and at a station 39ft. above the ground level. The latter part of the observation will be found of general interest. Looking at the register of rainfall collected at Nottingham during last year, we find that the greatest rainfall recorded in 24 hours was on July 25, when 1.152in. fell. The largest quantity recorded under “total rainfall per month” was in August, or 6.453in., and the least in March, .586in. The total rainfall in the 12 months is 28.842in. All the observations have been reduced to mean values.

A MEETING of the master brickmakers of the London suburban district was held on Monday afternoon, at the City Terminus Hotel, Cannon-

street, for the purpose of discussing the question of wages, and to decide as to the reduction to be made therein during the ensuing season. Mr. Rhodes occupied the chair, and stated that the matter had already been discussed at Wimbledon. In addition to the question before them, other questions might be considered, notably the one whether or not it was expedient to form a brickmasters' central association. Rating upon brickworks had now assumed a matter of considerable importance to them, since the whole country had been put under the operation of the sanitary laws, and consequently under sanitary rates. After some discussion, it was unanimously resolved that, in the opinion of the meeting, a general reduction of 6d. per 1,000 bricks should be made in the moulding price during the ensuing season. A committee was nominated to draw up a scheme for the formation of a central association, and report upon the same to an adjourned meeting.

MR. JOHN BURNS, of the Cunard Company, in a letter to the Provost of Glasgow, points out a reason why there is distress in that city. His company is fitting up a new steamship called the *Gallia*, and on Saturday the Belgian workpeople, who were laying down parquetry on the cabin floor, instead of leaving at one o'clock, as Scotch or Englishmen would have done, asked permission to go on till dark so as to finish their job:—“The entire panelling of the *Gallia's* cabin has been executed by Japanese carpenters, and the ironwork of the office in which I now sit was made in Belgium. Instance after instance could be given of how all nations are competing with us, not only as regards the manufacture of articles used in their respective countries—hitherto to a great extent supplied by Britain—but the artificers of foreign countries are, in spite of us, advancing into our own country, and compelling us to employ them, simply because they can do our work as well and much cheaper than it can be done by our own workmen. What does this bring us to but that the arbitrary curtailment of the hours of labour is a snare and delusion to our working classes, and the sooner they cast to the winds the doctrine of those who are imposing upon them the better for themselves? That doctrine tells the working man that he should not work longer than fifty-one hours in the week. That doctrine is nuts for the foreigner to crack, and is ruining our country and our countrymen.”

MR. C. R. ANDREWS, the surveyor to the Bournemouth Commissioners, has sent us details of house-drainage as required by the by-laws. The plan of publishing a sheet of sections and details is a desirable one, as there are many builders who are apt to disregard the written regulations. In the sheet before us a block plan for two houses, semi-detached, is shown with the position of the drains, soil-pipes, inlets and outlets for ventilation, road ventilators, &c. The sections show the mode of disconnection and the fall of house-drains, which is marked 1 in 20. In the details the soil-pipe is shown carried up above eaves, and there left open; the closets are connected with the soil-pipe, and the sink waste discharges on an outer gully. In the sections of

basement dry areas are indicated, and the walls are built hollow and tied with wrought-iron ties placed 24in. apart, and at every fourth course in height. Under the basement floor there is a layer of concrete and a space for ventilation, the walls have also concrete under-footings. Openings for ventilation are shown over every closet, and the waste-pipes are all discharged externally. The details are large and clearly drawn, and if the arrangements are carried out systematically, Bournemouth will enjoy greater immunity from infectious diseases than it has ever done.

A SKATING rink, offering 16,000 square feet of artificial ice in one sheet, is in successful operation in New York. This enterprise of Mr. Rankin is notable chiefly for its magnitude. Something like nine miles of gas-piping are required for circulation of the refrigerating liquid, which is pumped through after being in a freezing chamber some 250ft. long, where ice is liquefied by means of salt and other solids. The principle involved is simply that of the ice-cream freezer. A tight floor was laid over a surface 200ft. by 80ft.; on this floor a network of pipes was laid, and the whole flooded with two or three inches of water. The surface of the ice remains dry, though the atmosphere of the rink is warmed by half-a-dozen large furnaces. The temperature of the refrigerating liquid is said to be raised only 10 degrees while on its nine-mile journey.

GREAT precautions are being taken at Marseilles against entrance of the plague. More than two million francs have been devoted to quarantine arrangements and the storing of merchandise to be disinfected. M. De Lesseps has deplored these arrangements as fit to ruin the Compagnie des Messageries Maritimes without any compensating advantage. He thinks these quarantines powerless and useless. He recalls the circumstances of the destructive plague which he personally observed in Egypt in 1834; in Alexandria alone it caused 45,000 deaths in six months. M. De Lesseps affirms there was not a single case of transmission by contact, and where a village was attacked it was sufficient to remove the inhabitants, bathe them in the sea, and change their clothing, to make the mortality cease entirely. The plague, moreover, did not spread beyond Lower Egypt, though communication with Upper Egypt was not interrupted. M. De Lesseps desired the Academy to protest against the system adopted at Marseilles, as likely to rouse unnecessary alarm, &c. M. Bouley strenuously disputed M. De Lesseps' conclusions, and urged the analogy of the plague to cattle disease, which had been mastered in France by energetic measures (killing all affected animals, and keeping the frontier absolutely closed against those which were suspected).

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive of FEVERS, BILIOUSNESS, SMALL-POX, SKIN DISEASES, and many other spring and summer ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute.—ADVT.]

ROOFING SLATES.

Reduction in Prices.

Send for price list to THOMAS R. ROBERTS, Slate Merchant, Conway, before ordering elsewhere. Slate slabs, tiles, hearthstones, ridges, cisterns, and all other kind of slate work very cheap.—ADVT.]

LONDON.

JOHNSON & CO.

ARCHITECTURAL

RED AND BUFF TERRA-COTTA MANUFACTURERS.

Works: Ditchling and Keymer Junction, near Burgess Hill, Sussex.

J. & Co. have obtained MEDALS at the London and Philadelphia Exhibitions for GOOD DESIGNS and EXCELLENCE of MATERIAL and WORKMANSHIP, and will, on request, send samples of work.

RIDGE TILES, FINIALS, BRICKS, TILES, &c., which are hard in texture, smooth, and of a deep red colour, and will resist the action of the weather.

Architects' Designs faithfully carried out. Samples of Work, South Kensington Museum. Estimates on application.

THE BUILDING NEWS.

LONDON, FRIDAY, MARCH 14, 1879.

ART AND ARCHITECTURE IN JAPAN.

FROM no country and no nation in the world can Europe gain more teaching, in matters of art generally and architecture especially, than from Japan and the Japanese. The superb folio just issued from the Imperial Press, at Hahodadi, is one among the most remarkable illustrations of a combination of Western and Eastern ideas. It might have been more characteristic, perhaps, had it represented a purely Asiatic type; yet it becomes more historical as exemplifying a change from the primitive to the new. In a great degree, however, this rich volume deals alone with the past, and with the earliest stages of those inventions and manners which really constitute the first developments of civilisation. Thus, Japanese architecture: it occupies the opening chapter of the Japanese annals. There seems never to have been a time in those islands when men were content with huts of branches and caves as habitations, or with hollows in the rock as habitations. They did not possess, of course, the refinements or ambitions of Greece, or Rome, or Assyria, yet they could build castles vieing in strength and grandeur with the Norman, palaces of Italian grace and luxury, and private abodes abundant in both imagination and taste. But there was always, as the artists of the magnificent volume before us plead, one capital deficiency for which they could never atone. The Japanese group, notwithstanding all its other riches, possesses little granite, and no true marble. While, therefore, despising the resources with which the barbarian inhabitants of other regions were satisfied, the people of this region thought that they might "create an architecture, so to speak, out of wood. They made the attempt, and, in a manner, they succeeded. The plan was necessarily limited; the scope was confined; no edifices so reared could suggest the idea of secular duration; they could present neither grand vertical nor horizontal lines; they were built upon vast multitudes of piles, covered with immense shadowy masses of roof, broken into many curves and angles, distorted by eccentricities which in timber may be permissible, though they would be atrocious in stone, and yet the large effect, as set before us in chromo-lithograph, is not displeasing. We have a first, a second, and a third floor of buildings surrounded less by walls than by arcades—which give an appearance of lightness to the whole perspective—and, when the galleries of approach are really inclosed, they are usually made light and cheerful by gaily-painted paper. Something of a Pompeian character, indeed, pervades these vestibules and lobbies, although the human figures are far less graceful than the Greek, while the pornography is even more atrocious. There are doors opening upon windowless interiors, passages with wide-seated bays, looking apparently upon lawns of green, sprinkled with tinted beds of flowers, porticoes where none were to be expected, conducting to geometrical gardens, and immensely wide avenues without a curve, but breaking off at right angles into others, which deepen down into flat perspectives of forest-land. In all this we detect the universal tradition of Japanese, and, indeed, of Chinese and Mongolian art and taste, generally. It is naturalism in full freedom. "Why," asks one of the Imperial authors, "should we build cloisters, when all we want is plenty of air?" Still, other motives

must have been at work. Stone, as we have hinted, is not altogether wanting in Japan. It is the material of which the foundations of all the island temples are constructed; and it supplies the pavements of the more important towns. The Imperial report is seriously emphatic upon this part of the subject; and especial attention is drawn to the fact that the result of all this wooden architecture, if the term may be employed, is by no means monotonous. There are, in Japan, two classes of sanctuaries: the one formed of dull, unpainted, deal boards; the other roofed over with earthen tiles, variegated and fanciful, with crooked horns at every corner where it is found possible to place one. Under these, the church architects of China suspend bells; in Japan bells as appurtenances of such structures are forbidden. A gong, hung up at the gate, gives notices to the worshippers who may be waiting upon the ceremonial of the day. Half the edifice often consists of portico; beyond this a wall, pierced by a door, inside, as in the Greek temples, an almost too light interior. Here and there, square or rounded timber columns, sometimes a metal base or capital; between the pillars, huge curved masses of roughly-sculptured wood; in the centre, the solid trunk of a tree, surmounted by an elephant's head carved in pine. Between this and the base, however, occur ranges of fanciful decoration such as might do credit to the toy-makers of Nuremberg themselves, though the most remarkable circumstance in connection with them is the perpetual reproduction of the pyramidal, or flame-shaped, figure. Externally, moreover, a Japanese temple has its auxiliary appendages—an hyperboreal gallery, a fountain for religious ablutions, a miniature pagoda of three, four, or five stories, columns in couples, and almost purely Doric in style; lion-forms resembling those exhumed in Assyria, and stone lanterns which have no counterparts among the archaeological discoveries in any other place on the surface of this globe. Amid all this eccentricity, however, one feature is salient,—the disproportion between the height of the columns and the weight of the roof, aggravated, perhaps, by the roughness of the rude low arches, the grotesque attempts at carving, the singular suggestions of Roman and Gothic to be here and there detected, and the manifest association, everywhere, with the barbaric mannerisms of China. The Chinese were our masters, say the compilers of the Imperial Report, with admirable modesty, but they go on to plead that their chief material in architecture and art, with the exception of their inimitable lacquer, is the bamboo, out of which, they pathetically add, "we cannot be expected to rear either a Parthenon or a Pyramid." And yet they contrive to cut vast staircases from base to summit of their solid mountains, and their ancestors, at any rate, erected shrines of which the most exalted Buddhists in Southern India might be proud. And, in point of artistic taste, the Chinese have never been, within a hundred degrees, the rivals of Japan. These latter, too, are apt to lavish more of their wealth and their idealism upon their private lives than upon public structures. They care little, as a rule, for palaces or temples, any more than they do for costumes or jewellery; but upon their houses they bestow an art resembling in its perfection and passion, though not in its materials, that which was bestowed by the men "designing like Titans, and working like jewellers," who reared the tombs of Delhi.

No traveller or visitor from Europe has ever laid open so clear a perspective of this far Eastern artistic life, or, indeed, history, as it may more properly be called, as this official statement or avowal. It tells us of a fortress, reared ages ago, when the arts of quarrying and of monumental structure were

known in Japan, of high castellated towers, of large "frigate-shaped" fortresses hewn from the quartz rock; and, still more singularly, of arched bridges, almost exactly similar to those of which the Dutch imported the plans from Amsterdam, and built at Kagosima. The Japanese models were 300 years more ancient than their supposed models in Holland. The Japanese gardens attached to these palatial residences may be passed by, as not taking any prominence in the Imperial Report; but a strong stress is laid upon the art of garden architecture; the dividing walls between gardens and terraces; the bridges over lakes; the descending steps from mansion-gates; the position and form of fountain-groups; and the contrast between these Asiatic Paradises and those of Europe, with which their conservators seem perfectly familiar, at Versailles, Rambouillet, and Fontainebleau, the erections of Louis XIV., Colbert, Bossuet, and Lenotre. Viewed as a whole, the architecture of Japan, as set forth and indicated by its professional admirers, is an attempt at conformity with the religion, the climate, the customs, and the character at large of the people; but, apart from this, the Imperial folio descends to smaller particulars. It confesses the deep and everlasting want of all Asiatic art; its utter powerlessness to represent the ideal of human beauty. It has no sense of colour in the highest and noblest sense; it does not recognise mankind in its most graceful movements, its most majestic attitudes, in the expressions which have been given to it in marble or bronze, by the classic natives. Here, we think, the Japanese writers have struck a true chord, perhaps by the assistance of an understanding other than their own. They have never seen men or women otherwise than in a condition of somnolence or slavery, of degrading labour, or luxury more degrading still, and they have never seen a specimen of humanity which could suggest to them other than the notion of a grotesque and ugly god. Their "graven image," in fact, is Buddha, a thousand times repeated, but it may be contended that they often drape him with a grace and vigour not commonly characteristic of Eastern art, in which the earliest models are always those which are most frequently copied. Again, as the Imperial Report admits, they have to represent the one mighty figure of their mythology in all variety of colours and shapes—to conform with the popular superstitions, to be grime, deformed, contorted, a faun or a satyr, a goblin or a hideous idol, precisely to suit the ignorance and the fanaticism of his worshippers. There are, we are told, in the temple of Go-Hiakir-Balkan, at Yeddo, no fewer than five hundred of those images all varying in their ugliness and their utter opposition to every thought of art, yet all assembled round a central altar, typifying the same genius, or power, of good or evil—all kings, saints, and martyrs in their turn, according to the avatars through which they have passed. Colour gives to them, perhaps, their principal characteristic. Excepting the few colossal Buddhas in stone and bronze, the statues are generally of gilded or lacquered wood. The flesh is painted in a rose tint; the gilding is splendid when it reaches the claws, eyes, and teeth of mythical animals, and the beards, where golden, are marvellously suggestive of original massiveness and abundance. This, indeed, is a light thrown upon both the old and the new Japanese arts such as they were never seen in before. But the illustrations in our Imperial folio do not end here. They set forth, also, a vast variety of anecdotes and fables in water-colours, representing soldiers on horseback and on foot, hunters in armour or naked, nobles and princes at Court, priests before backgrounds of gold, ecstasies going through artificial miseries similar to those represented on Egyptian tombs, animals

ascending scaffolds or hanging on gibbets, wretches undergoing torture, chimerical lions, leopards, and birds, and, as a surprise, iodes, lakelets, pavilions, bridges, a peacock on a terrace, and a lady with a fan. There is also the picture of a Japanese artist's studio with his models, his boxes of colours, his little coffers full of vegetable and mineral pigments, his fish-skin varnish, his circle of Chinese ink, his pen-shaped pencils, his brushes of the finest hair, his two palettes—the one small, the other large—with a hole made in each for the thumb, a northern light through the window, and the artist himself "steadying his right hand with his left to prevent it from trembling." All this should be of great and original interest in these days. We have, too, an historical sketch of the engraver's art, as it was probably practised in Japan long before it was familiar in China, with a singular series of copies from the block engravings of Japanese composers; but among the whole the native instinct for colour must be regarded as supreme, whether it is exhibited in mattings or in tapestry, in carpets or in cabinet work, in lacquer or in porcelain. Even in the tones and tints of their gilding and enamels the artists of Japan display a sweetness, so to speak, and a tender gradation which, as the self-enamoured artificers of King-te-Chin themselves—their rivals—confess, "is not excelled at Verres." We may perceive from this how closely the scientific industries of the East and the West are being brought together, and how close the competition between them is likely to become.

THE INSTITUTE PRIZE DESIGNS.

IN looking over the designs contributed for the Soane Medallion and the sum of £50 at Conduit-street, no judge of architectural drawings can fail to recognise in the design of "I Strive," a very clever work exhibiting considerable power and artistic feeling. In the plan of the building intended for Four Learned Societies, the blocks are ingeniously disposed symmetrically about a centre axis, and considerable skill is evinced in the outline and grouping of the parts, despite some obvious defects in detail. The buildings are comprised within a long quadrangle, there being three transverse and four side blocks, leaving two inner courts, which have been cleverly treated. The reading and writing-rooms are on the upper floor, and occupy the two main transverse buildings, each with its own entrance and staircase, while the ground floor is devoted to council room, secretary's and clerk's offices. The connecting side blocks are made the libraries, while the building in rear is the lecture theatre, T-shaped in plan, with the seats arranged curvilinearly, and with side entrances from the inner courts. We admire the manner the staircases, which form large circular-bayed ends towards the courts, are planned, but the lobby and entrances look ill-lighted on plan and the clerks' entrances somewhat tortuous. The arrangement on the first floor is much better: the landing and vestibule are architecturally managed, and the rooms are pleasingly broken by bays, which externally produce a very piquant grouping, especially towards the river frontage. There are two bays on each side of a centre archway or entrance, which last feature is somewhat elliptical in curve, bold in effect, and enriched with several members. Less to our taste is the side elevation; the centre hipped roof portion harmonises ill with the lateral bays of the libraries, which are carried up too high, and filled with an unmeaning kind of lozenge panelling in the gables. The details of the river front bay windows are particularly refined, and the author has followed in the lattice portion the French Renaissance of a type, it would seem, between

that of the 16th century and the Grand Monarque, though some of the details are incoherent enough to belong to that of Henry IV. The author of this design (W. R. Lethaby, Barnstaple) has been a frequent contributor to the BUILDING NEWS. The next meritorious design for this subject is "Acropolis." The author has chosen Classic, of the Greek Ionic type; the lecture-room forms the centre of quadrangle, round which and vestibule is a corridor, the offices and council-rooms surrounding the latter. We hardly like the tower, or attic, over hall—it has rather a crushing effect upon the portico in front, though its sides have boldly arched openings. The flank elevation and the details generally show knowledge of the style and some refinement, and the ink drawings are well executed. "Classic" is the motto of another attempt to compete for this prize. It is a classical composition with heavy pavilions at the corners crowned by domical roofs, a loggia of open arches being between. The architecture is of a somewhat "loud" kind—if we may use the phrase—and the drawing, though vigorous in parts, errs grievously, we notice, in the perspective of the columns. The necks to the capitals are drawn with so much curve as to become positively glaring. The loggia-arches are also defective in their curvature, and more pains would have been better bestowed upon these little matters. Some clever detail, but sadly wanting in scale, is shown in the lecture-hall detail. The author's upper plan is not without merits. The lecture-theatre is placed crosswise in centre of rectangle, and the reading-room and libraries occupy the angles and sides. "Spes" is another design, but in a feeble Gothic. Passing to the Grisell Medal designs for the construction of a stone dome over a drum of 40ft. diameter, Mr. G. H. Blagrove, of Southampton-row, wins the prize. The author's drawings are carefully worked out, and the constructive details are shown. We observe the author explains in full the "theory of stability," according to some of the best authorities—a practice we must certainly commend, as showing the candidate's knowledge of theory. One or two other designs for this very excellent prize are exhibited, but of a kind which only indicates the value of this recent addition to the Institute scholarships. The "Tite prize" does not go begging, but we should like to have seen a little larger display of good drawings. The year the prize was offered for a design for a building at the angle of two streets, combining a first-class shop, show-rooms on entresol and first-floor. Mr. C. E. Sayer, of Soho-square, carries off the honour. The design, if we cannot accord it high praise, is well drawn and shaded in India ink. It shows a circular corner domed above; the treatment does not strike us for its originality so much as its careful and moderate use of ordinary features. A space is left for furniture, and there is a spiral iron stair to the show-rooms. Another design, "Patentia et Spes," by Mr. H. A. Pelly, showing a refined treatment of elevation and some good detail, is recommended for medal of merit. Honourable mention is awarded to "Acanthus," by Mr. F. Edwards, of Manchester. On a first view, the elevation is commonplace, but the entresol is cleverly treated by a transom subordinated to the rusticated ground-story piers, which embrace both stories. The upper part of composition savours of tameness. "Italiano" and "Spes" are two other designs, but both wanting in knowledge and moderation in the use of ornament.

The Pugin's Travelling Studentship has fallen to a gentleman who, it must be said, gives evidence of both ability and perseverance though a comparatively new competitor for architectural honours. A glance at the drawings, hung and in portfolio, is enough to convince us of both of the above-men-

tioned qualities. Mr. Walter J. N. Millard is the successful candidate. His drawings and sketches in France and Belgium, chiefly in pencil, show a considerable capacity. We notice, for instance, his "Sketch-book Leaves," in which there are some charming scraps of buildings, such as Winchester Cathedral and the sketches showing that unique example of a Mediaeval fireplace at Netley Abbey. The design for a street front of ordinary dwelling-house shows a suitable brick treatment; but the most charming of Mr. Millard's sketches are his water-colours. The bits of natural scenery from Twickenham, Richmond Park, Selhurst, &c., are extremely clever studies of vigorous and honest handling in colour. The sketch of Chingford Church, with its rich yew-tree, is very truthful and clever; the round-headed tree in the sketch from Selhurst is also a capital study of foliage. In this work of art Mr. Frederick Hemings, who is awarded honourable mention, follows close to Mr. Millard, and both gentlemen have gone, it would seem, to the same fount of inspiration, and have been inspired with much the same feeling. The pencil sketches from Beauvais, Laon, Soissons, &c. are very interesting. In the same competition, Mr. J. Lansdell contributes some excellent and painstaking sketches in ink, showing considerable feeling and delicate handling. We refer to his sketches from Soissons and Laon, as examples. Mr. G. H. Raynor sends some very careful and creditable work; and Mr. J. Nixon Horsfield's drawings are clever, and we observe this gentleman is the recipient of the same studentship of the Manchester Architectural Society. We cannot omit to mention the excellent drawings from the Antique, sent by Mr. F. Miller—certainly more his forte than architectural drawing. We must also mention some capital pen-and-ink drawings by John B. Guss, a sketch of "Hall i' th' Wood," Bolton, a fine specimen of an ornamental timber house, recently illustrated in the BUILDING NEWS, and drawings of Glasgow Cathedral and Dryburgh Abbey, by James Lindsay. The Institute Silver Medal and £5 5s., for measured drawings, has been won by Mr. F. Pinches, of the Strand, for some carefully-executed drawings and details of Melrose Abbey, in which there is much feeling, though want of decision. Mr. Sidney Vacher, of Kennington Park, also obtains mention for his drawings of Lincoln Minster, showing a bay of the Angel choir, the drawings of which are rather spoilt by the bright colours used in the sectional parts, which rather detract from the work. There are some other drawings displaying considerable merit, to which we cannot here refer, though they are the work of students destined in a few years to take the place of their more experienced and fortunate competitors. Perhaps the misfortune in all these competitive contests is that of doing too much, if not in squandering valuable time on worthless examples, which, because they are old, are thought worthy of all the votary's labour. There are many instances of this want of judgment in the drawings under review, which occupy, in addition to the four walls of the Association lecture-room, three large screens and numerous portfolios.

THE SCOTTISH BROCHS AND THEIR ORIGIN.

IT is only fair that, having given, in a recent article, the gist of the arguments of Mr. Fergusson in reference to the origin of the Brochs in Northern Scotland, we should now lay before our archaeological readers Mr. Anderson's inferences; and we are the better able to do this from having received a reprint of that gentleman's paper from the "Proceedings of the Society of Antiquaries of Scotland." Mr. Fergusson

maintains, as we have shown, a Norwegian origin for the Brochs; while Mr. Anderson argues that these peculiar circular erections are Celtic, being allied in their structural peculiarities to Celtic monuments. Mr. Fergusson having recently challenged the full discussion of the subject, after Mr. Anderson's paper in the 5th volume of the "Archæologia Scotica" appeared, it is not unreasonable that Mr. Anderson should now desire to strengthen his theory. Mr. Anderson's paper is entitled "Notes on the Structure, Distribution, and Contents of the Brochs, with special reference to the question of their Celtic or Norwegian Origin." The author reviews the evidences derived from structural peculiarities, geographical range, and the contents of the Brochs; also their relation to other antiquities in the North of Scotland. It will be impossible here to devote the space necessary for a complete recapitulation of the arguments; so we shall confine ourselves to a brief *résumé* of the principal of them, leaving our readers to draw their own conclusions. We may observe, the paper is well illustrated—a view and plan of the Broch of Mousa, Shetland, with section, being given as a typical example. This is a circular tower, with hollow walls built of masonry laid dry, about 60 feet in diameter, and 50 feet high. Its wall, 15 feet thick, is solid for about 8 feet, above which it is hollow, the cavity being 3 feet wide between the two shells. This hollow space is crossed by slabs at about the height of a man, forming floors or galleries which run completely round except at the stairs, each gallery opening in front of the steps, its other end being closed by the back of staircase on the same level. An outer opening, the only one, is a narrow tunnel-like passage 15 feet long, 3 feet wide, and 5 to 6 feet high. The central area or well is surrounded by entrances to the chambers on ground floor. The section shows the tower to be a truncated cone, with a curved batter outside, pierced only by the narrow doorway; while inside the court low and narrow openings give access to the chambers and stairs, and a long vertical opening, divided by slabs, ladder-like in appearance, admit light and air to the galleries. The author defines the geographical limits of this typical structure, and gives a list of several which vary in dimension from 34ft. to 90ft. external diameter, and maintains (1) that no Brochs are found in Norway or in any of the Viking colonies, except Northern Scotland, though Brochs are found in the Celtic as well as in the Norwegian area of Scotland, (2) that no dry-built stone edifices are known in Norway, though such structures are characteristic of the Celtic, or early Christian period of Scotland and Ireland, (3) that there is not in Norway a single specimen of a vaulted roof of dry-built masonry in any ancient dwelling or tomb, though such roofs are characteristic of early Celtic structures. In answer to Mr. Fergusson's argument, that the Brochs were useless for offensive warfare, the author says "the warfare of this region was peculiar. It was an irregular, intermittent warfare—a succession of forays by marauding bands against which there could be no more effective system of defence than a multitude of safes which were burglar-proof, and big enough to contain the families' goods and cattle of the joint proprietors. But the peculiarity of Mr. Fergusson's theory is, that it obliges him to give the safes, to the burglars, and not to the people whose property was continually threatened." Referring to one structural objection raised by Mr. Fergusson, the author remarks:—"I cannot adduce more authoritative testimony to the fact that the Northmen of the Viking time (8th to 11th century) were unskilled in constructing edifices of stone than that of M. Nicolayson and M. Lorange," who maintain that it was not till the introduction of Christianity, or

the beginning of the 11th century, that lime and stone were employed, and therefore that the Northmen of the Viking time were still in their timber age. Mr. Anderson also says the Brochs are not all located in the sea margin, but are situated on inland lochs. In Caithness they mark the area of the best land, and in Sutherland are thickly planted in the fertile straths following the course of rivers, and far from the sea. Coming to the contents of the brochs, Mr. Anderson speaks with more authority. He observes: "If the brochs were built by the Norwegians, the relics found in them being the refuse of Viking life ought necessarily to correspond in character with the remains of the same period found in Norway and in the rest of the Viking colonies. Yet nothing is more certain than that this well-marked Norwegian group is not distinguishable among the extensive collections obtained from the Brochs, while nothing is more obvious than that the general *facies* of these collections from the brochs agrees completely with the remains of the late Celtic or post-Roman period from other parts of Scotland." Many engravings of an interesting kind are given to prove this conclusion, such as the long-handled comb (not unlike a human foot) found in the Brochs, but not found in Christiania or Stockholm Museums, whereas the characteristic Viking bowl-shaped brooch has not been found among the Broch relics. Various stone utensils, called "lamps" by the author, are figured, which he shows to be peculiarly Celtic. On the whole, the Broch relics are indeed poor—a character in keeping, it is affirmed, with the desperate struggle for existence which the Celts were maintaining. On the other hand, the author admits that relics of Norwegian origin have been found in connection with these Brochs, the result, he asserts, of a "secondary occupation" of them, indicated by certain internal and external constructions of a different kind of masonry from the original structures. Mr. Fergusson ignores these. We cannot, however, go further. Mr. Anderson next examines the structural antiquities associated with the Brochs, and concludes that the chambered cairns are earlier than the Brochs, and therefore cannot belong to the Viking time, and have no analogy with the tumuli of Norway. This portion of the paper is amply illustrated, and we refer the reader to it. The chief conclusions of the author are, that the Brochs are allied by their structural characteristics to the Celtic, and not to the Norwegian group of stone monuments, in which no instance of a vaulted chamber occurs; that the Norwegian remains from graves of the Viking period in Scotland agree with those in Norway; that the relics of the Brochs agree with the post-Roman relics of Celtic Scotland; and that the Viking origin of the other antiquities is not supported by satisfactory evidence.

THE HOLBORN UNION INFIRMARY, HIGHGATE.

IN an open space facing the Whittington Almshouses at Highgate, between Holloway-road and Hornsey-lane, an important group of buildings for the Holborn Union Infirmary has been erected from the designs of Mr. H. Saxon Snell, a bird's-eye view and plan of which we illustrate to-day. Mr. Snell, who has only partially adopted the pavilion principle of plan, has placed his main blocks to form three sides of an elongated quadrangle. From an inspection of the buildings, we must admit that the architect has well complied with the requirements of the Local Government Board, and that the wards are well separated and admit of easy administration, while the grouping of the blocks presents a dignified exterior to the main road. Two main blocks of wards of five stories in height, separated by a central

tower and staircases, compose the façade. The windows have been combined in vertical recesses between the piers, and are effectively pronounced by gabled heads which form the most pleasing feature of the elevations. These are built in stock brick, without coloured bands or other unnecessary ornamentation, and are characterised by an agreeable breadth of treatment. The lavatories, &c., are boldly pronounced features and terminate as towers which help to break the monotony of the masses.

As the plan we give will show, the hospital comprises a central block, which forms the principal façade, at the ends of which, though separated and communicating only by a covered corridor, are detached pavilions at right angles, and these form advancing wings in the main front. Parallel with and in front of the central block, and connected with it by the main centre entrance, are the officers' quarters. These are the principal blocks. To be more particular, we may say the central or main block forms two wings and centre, one wing devoted for male and the other for female patients. If we describe one of the wards comprised in a wing the whole of this block will be understood. Each ward, then, is 100 feet by 40 feet, will contain 50 beds, and is divided into five parallel compartments transversely to the main length or axis, each being pronounced by a bay window at the south-west side, so that externally on this front the elevation consists of a series of five bays to each wing which continue through all the stories. The advantages of these bays are obvious. They give an ample supply of light and air to the ward; they catch the sun, so invaluable as a curative agent, and they form a series of cosy and comfortable recesses for patients to sit in. Every bay is surrounded by a seat with sloped backs of pitch pine; in the centre will be a table, and the space thus set apart answers the purpose of a day-room to the group of patients in each compartment of ten beds. The beds are arranged in rows at right angles to the length of the compartments which are separated by dwarf walls about 5ft. high and iron columns. The sides opposite the bay windows have casements and hinged top lights. At the extreme end are three closets, a sink, bath, and lavatory, arranged with a ventilated lobby in the approved plan. At the other end, the centre of the whole block, is the staircase and nurses' room. Of the sanitary ventilating arrangements we can speak favourably. Fresh-air inlets are introduced at the end of every compartment; these will communicate with skirting-boxes having perforated zinc panels, and running under the beds, through which also a hot-water pipe runs. The outlet openings are at the sides of windows, are covered with perforated zinc, and communicate with flues in the piers of wall. Besides these there are ceiling channels at intervals which allow the vitiated air to escape by other flues in the walls on each side. In these channels are the pipes to carry off the products of combustion from the gas-burners, the latter being suspended with inverted cup-like receivers. As regards warming, in addition to the hot-water system, "Thermohydric Stoves" are placed between the bays, the flues of which are carried up the walls. The walls are plastered, the lower part in Keene's cement and coloured French grey and chocolate red below. Hydrants are provided on every floor, and linen-cupboards and nurses' scullery on the landings. The bay windows have sliding sashes. We may observe that the entrances to the several wards are by the staircases in centre, one to each sex, and that no opening occurs between except at the top landing, where a door for the convenience of the medical attendants is made. The main entrance under tower is a wide-arched corridor with receiving wards on each side. In the basement under the wards are stores

and officers' pay and mess-rooms arranged *en suite*. A lift is provided to the several wards, and the whole length of basement is traversed by a tramway which connects the end pavilions with the main block. Each end pavilion forms a long narrow block at right angles, as we have said, to the central one. At one end is a staircase and lift, nurses' room with plate rack and observation-window, and a small ward for four beds for special cases with its own conveniences; the other portion forms on each floor a ward for 28 beds, 84 feet by 24 feet, with windows on both sides and rows of beds in pairs. At the north-east end is a semi-detached projection or tower, comprising a sink and two closets, lavatory, &c., and having a lateral window for cross-ventilation. In each pavilion this forms a tower. The other ventilating details are the same as those described above, namely, inlets near floors with perforated zinc skirting boxes under the beds for the hot pipes, &c. We notice that the windows in these wards have casements as well as upper sliding sashes, and the architect has managed to secure sufficient depth of window-sill to obtain outer balconettes that may be used by patients. Two Thermhydic stoves are placed in the centre of each ward.

Between the end pavilions, and parallel to the central block, is a range of officers' quarters. These are connected by a central covered way. The doctor's residence forms the centre of the range, and comprises large reception-rooms and several bedrooms. A Board-room is provided over the entrance hall. The matron's and head nurse's rooms occupy the remainder of the wings, accommodation for 26 nurses being provided. The central tower is carried up and forms an imposing feature in the principal façade. In the upper story is a large iron tank 10 feet square and 10 feet deep, holding 6,500 gallons to be used entirely for working the lift. The roof is of slate, and forms a low spire. Ascending to the upper gallery, and getting through the dormers to the parapet, a splendid panoramic view is obtained of the north of London and the Highgate hills. We notice that all the roofs are covered with green "Eureka" slates, and have red tile hips and ridges, contrasting agreeably with the stock brickwork. The walls are relieved by Malin dressings and Beart's bricks in the copings, parapets, &c., stone being used as lintels. The chief effect is obtained by recessing the window bays, which are arched above, and break the roof as gables, the angles having a bold roll member of moulded brick. The parapets are pierced with vertical openings. We may add that the contractors are Messrs. J. Mowlem and Co., the engineering works having been carried out by the following firms:—The cooking apparatus by Messrs. Benham and Sons, the hot-water heating by May Bros., the lifts by Messrs. Potter and Sons, the gas by Messrs. Jeal Bros., and the w.c. apparatus by Mr. E. Howard. The works have been superintended for the contractors by Mr. W. C. Morey, Mr. Walter E. Blake having acted as clerk of works for the architect, Mr. H. Saxon Snell. We believe the entire cost of building will be about £80,000.

Many readers will feel flattered to hear that a daily journal considers the wedding-cake provided for the Duke of Connaught and his wife by a Windsor baker, "a very triumph of architectural skill and taste." We regret our space does not permit a reproduction of the description of the "structure," with its "vaulted roofs, supported by Corinthian columns," &c.

The Morley Clubhouse was opened at Nottingham on Friday evening. It is a large building situated at the corner of Shakespeare and Melbourne streets, and is of four stories, the ground floor being arranged as a café, with rooms for the Morley Club and Young Men's Christian Association above, and at the top a series of bedrooms. Mr. R. C. Sutton is the architect, and Messrs. Thomas Fish and Son are the builders.

HOUSEHOLD SANITARY ARRANGEMENTS.—IV.

IN his fourth Cantor Lecture on "Dwelling Houses: their Sanitary Construction and Arrangements," delivered on Monday evening at the Society of Arts, Dr. Corfield took up the subjects of filtration of water and dry systems of removing refuse matters. The process of purification of water by filtration was, he said, until recently misunderstood. For a long time it was thought that water, in passing through a pervious material, was simply mechanically strained to the extent of separating from it the grosser suspended particles. When it was noticed that some of the dissolved matters were eliminated from the filtered water, it was still supposed that these accumulated in the filter, and that they would in time choke it up. The action of a filter was, however, not only to strain the water, but so to subject it, when finely divided, to the action of the air, that organic matters, whether suspended or dissolved, were oxidised by it and changed from putrescible substances to minerals no longer liable to change, and incapable of affecting the health of those drinking them. These facts explained the reasons why filtration, to be thoroughly effective, should be both downward and intermittent—downward, because then the water descended by its own weight in minute streams, and was less likely to be forced through the porous material *en masse*, driving the air before it; and intermittent, to give time to the filtering substance to re-absorb air in place of that used during the purification of the water. A compensatory advantage of upward filtration was that when it was adopted there was some guarantee that all the water had actually passed through the filter. In illustration of the necessity for sharply looking after all household filters to insure that they were in good order and in use, Professor Corfield mentioned that a London medical man, who was very particular about sanitary matters, suspected that the filtration of his drinking-water was not so thorough as it ought to be. On examining his cisterns he found that the filter had been carefully adjusted so as to purify the water passing into the servants' water-closets, whereas the domestic supply for drinking purposes was not submitted to the process.

Having explained the principles of filtration by familiar illustrations, and referred to Dr. Frankland's experiments, the lecturer proceeded to describe a number of filters exhibited on the table. In those of the London Water Purifying Company the water passed upwards from the large cistern through pores in a vase; from thence it passes out at the top through a little cup full of holes, and so into pipes by which it is drawn off into the pipes upon the siphon principle. In these filters all the water used must have passed through the filter, and it would continue in action for an almost indefinite period.

Concerning the silicated carbon filter the opinion was pronounced that the filtering material was exceedingly good, not being liable to contain living organisms. For filtering purposes both animal and vegetable charcoal were employed. The latter material was very inferior—it not only gave off salts into the water but was less effective in straining the liquid. Animal charcoal was not always sufficiently burnt; and when any animal substance remained uncalcined in the centre of the cake of charcoal, it became a breeding-place for minute red worms. In using charcoal, therefore, it was necessary to see that it was of animal origin, and that it was thoroughly burnt. It ought to be frequently cleansed, and occasionally scraped. Sponge was often used, as it was an exceedingly unalterable substance; but it needed more frequent washing, or, better still, should be replaced at short intervals, as it harboured small worms. In too many filters, much of the water passed over the surface only of the porous material. The best forms of charcoal filter were those in which two blocks were used, the first acting as a strainer. A well-known charcoal filter was Atkins', known as the Admiralty pattern, of which several varieties were shown. In almost all filters the water should be run off every night, to allow of re-aëration. This must not be done with the spongy iron filters of Bischof, in which the material must always be kept under water. By means of diagrams and specimens, the action of these filters was ex-

plained, it being shown that the water entered the filter by a ball-cock arrangement, and passed down by a tube to near the bottom of the vase; it then rose through holes in a plate through the spongy iron, and was drawn off at the top. In passing through the iron the water took some of its particles up, and was, therefore, afterwards run through a layer of prepared sand. In order to aërate the water, it was next spouted through a minute hole, falling as spray into a pure-water reservoir. The principles of action of this filter were not yet clearly understood, but its results were the destruction of organic substances in a different manner to that effected by using either charcoal or sand. In the aërating filter of the Sanitary Engineering and Ventilating Company, the air that passed out of the pure-water chamber rose through the filtering material, and hence there was no need of the tube for the exit of air provided in almost all filters. In this filter, water passed into a loose vase, and through a cake of silicated carbon, being subsequently squirted upon other loose filtering material. The plate supporting this second mass, instead of being flat, as in ordinary filters, was raised in parts, with small holes both in the elevated and depressed portions, so that the air displaced by the water escaped through the higher portions of the plate. For use in a room, the common glass vase containing a cake of charcoal was suitable, as its perfect cleanliness could be seen at a glance. An improvement was a handle to the upper vase, so that when raised it did not drip. A good method for filtering rain-water, for use in country places, was that designed by Professor Rolleston, of Oxford. It was a tank divided into a large and small compartment, with a layer of filtering material passing through both divisions, and resting on a perforated frame. The rain-water was received near the bottom of the smaller compartment, and, rising through the filtering medium, flowed over the diaphragm into the large compartment, where, passing by gravitation through the second filter-bed, it flowed away. The water was thus subjected to both upward and downward filtration. A waste-pipe, to obviate overflow, was an essential to this filter.

The lecturer then passed on to his second topic, the removal of refuse from houses by "dry systems." "Dust" ought to be nothing but what its name imported, household dust and ashes; but, as a fact, all kinds of refuse found their way to the dust-bin, creating much nuisance. All organic refuse from the kitchen ought to be placed on the kitchen-fire at night, when it would help to light the fire in the morning, and would be inoffensive, as everyone could see by experiment. The difficulty of dealing with dust was a growing and an increasingly expensive one. A few years since, when it was largely used for brick-making, it was a valuable product, but now, contractors, instead of offering considerable sums for the privilege of removing it, required payment for taking it away. Thus, at Islington, the contractor a few years since offered £2,200 a year for the dust, and this year the accepted tender cost the parish £4,057. One of the first sanitary laws was that all refuse matter should be removed as speedily as possible, but owing to the expense of carting away a valueless material our dust-bins were emptied as seldom as possible without becoming an absolute nuisance. Where practicable, dust-bins should not be allowed to abut on the walls of a house, and in no case should a rain-water pipe be permitted to pass through them; much injury to health resulted from a combination of these errors. If the space was so limited that the bin must rest against the house, it should be well cemented to prevent the percolation of air through the walls, and a rain-tight cover (happily made compulsory in the metropolis) should be fitted to it. But he must pass on to speak upon our methods of treating excretal matters in, and their removal from, the house. The very name of these methods, "conservancy plans," was self-condemnatory, for the householder's aim should be to get rid of excretal and other refuse as speedily as possible. The first of these methods was by digging pits or cesspools in the adjacent ground, or even under the house, as a receptacle. When these were in fashion, it was thought so much the better if the soil were porous, for then the liquid matter would drain off, and they would need emptying the less often. The inevitable result was, that in loose soils the wells became contaminated, and cholera and typhoid and other fevers prevailed. Opinions changed, and cesspools were

afterwards made with impervious walls, so that the contents were kept in, a connection being sometimes made with a land drain or sewer. The last modification was yet largely practised in Paris for the sake of the manure; in that city, as visitors had seen, open-mouthed pipes passed from every floor to the cesspool, and as the only ventilation was by pipes to the roof level, the method was exceedingly offensive. In that city the receptacles were emptied by means of airtight carts, previously exhausted of air, and attached to the cesspool to suck up the contents—a practice no one who had observed it in operation would wish introduced into England. In many parts of this country the dust-heap was made the receptacle of all refuse, the liquids being absorbed by the ashes. In some towns these "middens" were of enormous size, as in Liverpool, and were even suffered to accumulate in the houses. Wherever they existed the mortality, especially amongst children, was very great. The improvements in these dry systems were always twofold, consisting—first, in making the receptacles smaller; and second, in rendering them impervious to water. The first alteration necessitated more frequent cleansing; the second insured that the refuse should be less liable to moisture—one of the essential conditions of decomposition. Cesspools were, as knowledge of sanitary laws increased, reduced to movable receptacles, as in many parts of France, and the liquids were allowed to pass off into drains and the solids removed, as in Cheshire's system. Pails and tubs were placed below the seats of closets, as at Edinburgh, Manchester, and Birmingham. The danger of these plans was that these foul substances were allowed to remain in the house too long. Such receptacles should have a spring lid, with indiarubber edges, to enable it to fit as tightly as possible. At Hull, a watertight receptacle was placed beneath each closet and periodically removed, and even this small improvement had led to a reduction in the death-rate of that town. Dr. Bayliss, medical officer of health for West Kent, had devised a shaft rising from the receptacle above the roof; the lecturer had examined instances of it in use, and considered it worked well in cottages. Morrell's self-acting cindersifting ash closet (of which a model was shown), had attached above and behind the closet a receptacle for cinders, of which the larger ones were retained in a sieve, and might be re-burnt. By the movement of the seat the ashes were sifted and fell into a hopper, being jerked upon the deposit when the seat rose, and so rendering it comparatively inoffensive. An undoubted advantage in this closet was that it separated the large cinders for re-use on the fire. The Goux system consisted of a double pail placed beneath the closet, having an absorbent material between the two pails. The dry-earth system was brought into prominent notice by the Rev. Henry Moule. He pointed out that dry earth formed a perfectly odourless compound with excretal matter, and that it could be used again and again if redried. For large communities, however, the system was perfectly impracticable. First there would be considerable difficulty in procuring in large towns a sufficient quantity of dry earth. Then there would be further difficulty in getting rid of the compost, owing to the fact—only admitted after considerable experiment—that it was not a valuable material manurally. The organic substances were so decomposed into their constituent carbonates and nitrates, some of the latter being probably given off as free nitrogen, that after the earth had been re-used six or seven times it possessed no greater agricultural value than ordinary garden mould. An insuperable objection was that in towns it would be liable to be used by careless persons, who would let slops and other liquid refuse mix with it, and so hasten decomposition, and the apparatus itself might get out of order. There was also the peril, the extent of which was yet unknown, that although the substances were deodorised they might not be disinfected, and so might propagate disease. The system was, however, the best for temporary collections of people, as at volunteer encampments or cattle shows, and might be used in isolated country houses. A similar system had been adopted for ages in China, and had been the means of enabling that land to maintain an enormous population without rendering the whole country barren. Professor Corfield announced, in closing his address, that in the next two lectures the water carriage systems of removal would be considered.

THE GREEK CHURCH AND THE NEW SYNAGOGUE AT BAYSWATER.

TWO buildings remarkable for their design are now in progress and near completion within a short distance of each other in Petersburg-place, Bayswater. One is the new Greek church, from the design of Mr. John Oldrid Scott, of which we gave a perspective view and plan, p. 442, Vol. XXX., and the other is a new synagogue from the joint design of Messrs. W. and G. Audsley, of Liverpool, and Mr. N. S. Joseph, of Coleman-street, also illustrated in the *BUILDING NEWS*, Vol. XXXIII., page 28. As representing two important religious communities, and as typical in architectural style of their respective tenets, we consider them as calling for a more than ordinary notice. Mr. J. O. Scott, in the Greek church, true to the traditions of the ritual, has taken the Greek cross as the form of the plan, three short arms and the apsidal chancel end. The western arm or transept has a narthex along its whole width and two entrances. The Byzantine style has been adopted, the centre area being covered by a dome of the same diameter as the transepts' width—namely, 42ft. The illustration which we gave will convey a good idea of the general effect and massing, though we remark a few deviations from the plan and design. One is the omission of the columns in the north and south transepts, and the dome is pierced not by triple dormers as shown, but by a regular series of equi-distant openings round the base. Externally the walls are of stock brick, relieved by bands of red brick, stone being introduced with red brick in the voussoirs of the arches. The narthex towards Petersburg-place has entrances at each end, the square-headed architraves of which are of polished granite boldly moulded, above which the semicircular arches divided by stone pillars. Above the central portion of the narthex, a gabled projection from the main wall of transept is built, forming a gallery lighted by a large circular-headed window, divided into four lights by square stone pillars, which are carried through a moulded transom to the arch-head. Above the two doorways domical roofs are formed in the angular recesses. These and the central dome are covered with lead laid in ribs. The external effect, it is needless to say, is somewhat heavy and lumpy, characteristic of all buildings of the Byzantine cupola class. Interiorly, although yet without the marble casing and coloured decoration to the domical surfaces and lateral vaults, the effect must be pronounced satisfactory. The dome rising from four wide arches that span the transepts, the central piers of Shap granite, and the broad wall surfaces produce a majestic ensemble. Each of the transepts is 42ft. in width, and is vaulted in concrete, while the eastern end is triapsal, divided by massive marble-cased pillars, the central bay being the widest. These are arched below, a circular relieving arch spanning the whole width of chancel, composed of voussoirs of alternate stone and red brick. Four pendentives fill the arch spandrels, above which is a circular cornice of terra-cotta, and five feet height of drum, from which the dome springs. The lower portion of cupola is of brickwork, a brick and a half in thickness; above it the cupola is constructed entirely of concrete, of hemispherical section, varying from 1ft. 2in. to 9in. at the crown, with an internal diameter of 42ft. Narrow openings pierce the dome round the lower part, and the whole inner surface is now simply plastered. The cupola was constructed on a ribbed centreing, and is surrounded at the haunches by a band of iron on the outside. Boxed girders are introduced across the angles within the pendentives, and the latter are further strengthened by iron bolts in the thickness of brickwork at angles. The whole forms, in fact, a solid, homogeneous and compact shell of brick and concrete, not the slightest apparent fracture being noticeable. We observe iron ties are introduced at the springing of the main arches, though these are hardly necessary for further security, now the work has become solidified. It may be mentioned that there is no outer roof or covering, the outer dome becoming at once the inner cupola or vault. The circular-ended apses have also semi-cupolas over them, and in the centre one a cartoon of Our Saviour has been placed on a gold ground. Of course, it is intended to adorn the main cupola and pendentives with frescoes; but we hear the

designs for these have not been settled. The four main piers, with their angular breaks, are encased with a rich dark green marble, and have bands of a black-veined marble at intervals. The walls are to be lined with marble slabs, and black vitrified brick courses project at irregular intervals of height for this purpose. The arches have alternate voussoirs of red brick and stone, and the capitals to angle piers are carved in Bath stone, their design being very similar to the caps of the main order at Sta. Sophia, Constantinople, from which, evidently, the outline, volutes and leafage have been inspired. Red terra-cotta abaci are above the caps, and we may remark that the whole of the terra-cotta enrichments are highly creditable to the manufacturers—the "Architectural Terra-Cotta Company." The chancel is raised three steps, these being of light marble. The altar of brick, encased in marble, stands in middle of the centre apse. An elaborate and carved wood-screen is to be erected across the chancel. In conformity with the usage of the Greek church, which forbids instrumental music, a singing gallery of slight projection is erected in the north transept, and we had the satisfaction of noticing the acoustic merits of the building by listening to the vocal powers of a gentleman who sang from this point. The transepts will be seated, the other portion of floor being paved with marble. Light is obtained by narrow semi-circular windows in the sides of transepts and by circular wheel-windows of terra-cotta in the gables. There is a large vestry and a lecture room below the south transept. We can only add that Messrs. Kirk and Randall, of Woolwich, are the contractors, Mr. Leake the foreman, and Mr. Leigh the clerk of works, the cost being estimated at about £15,000.

The new synagogue has a wide frontage to Petersburg-place, and is about 100ft. in length. The principal front—a view of which we gave—is of red brick with Mansfield stone dressings, and the architects—Messrs. Audsley and Joseph—have selected a style between Saracenic and Byzantine, if we are to judge by the details; the authors call it Græco-Byzantine. The main features of the front are—a richly-recessed arched doorway, subdivided by a shaft into two, in the arch of which is a sexfoil panel with the Decalogue inscribed; a large and elaborate traceried wheel-window, deeply recessed under a cusped arch, and a low gable with pierced parapet, flanked by turrets of minaret proportions, having cupolas of pointed shape. On each side is a low wing forming the ends of vestibule and the staircases. The vestibule is adorned by clusters of stone pillars, and have staircases at each end leading to the galleries. Passing the inner doors the interior presents a church-like appearance, having a nave and two aisles with galleries. The former has a clerestory of circular windows, and is covered with a plaster vault, ribbed and pointed. At the east end is an apse-like recess filled by a costly shrine of alabaster and marble, richly overlaid with gold, standing upon a raised marble platform of several steps. It is intended as the ark (*aron hakkodesh*), above which is the choristers' gallery, hidden behind the gilt cupolas which crown the ark. The platform or reading-desk at the west end of nave is also of variegated marbles, profusely gilded in the caps, &c. Over the choristers' gallery in apse is a large wheel-window, corresponding with that at west end, filled with stained glass. The side galleries are supported on massive octagon pillars of iron, which above the gallery fronts have very deep capitals east in plaster and intended for decoration. Above these spring moulded and enriched arches, of pointed horseshoe form, carrying the clerestory walls. The fronts of galleries are divided by small square black marble shafts with caps into narrow panels of very rich grained pitch pine polished, the effect of which resembles a fine yellow-toned marble. The seats, doors, and fittings are of the same material, simply varnished. As customary in the Jewish synagogues, the women are separated from the men, the galleries being set apart for the former. Throughout the workmanship is of excellent quality, and the walls are finished, of a cream colour. We notice some chastely-designed brass pendant gas burners, suspended from brackets in the spandrels of arches, and the whole of the fittings display considerable taste. The passages are laid with mosaic. The synagogue will hold 900 worshippers. Mr. Adamson, of Hammersmith, is the contractor.

THREE COTTAGES.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ILLUSTRATIONS FROM SIR GILBERT SCOTT'S "LECTURES ON MEDIEVAL ARCHITECTURE."

By permission of Mr. Murray, we present our readers this week with a double-page of illustrations culled from Sir Gilbert Scott's recently published "Lectures on Medieval Architecture," lately noticed by us. The principal example we give shows the eastern portion of Chichester Cathedral, one of the most beautiful instances of the Transition referred to in the author's third lecture. In a footnote Sir Gilbert Scott observes: "This work at Chichester was executed at the close of the [12th] century, after the fire of 1186, but Professor Willis has shown that some early pointed work of a very marked character, which exists in the western part of the Lady Chapel, must have been erected previously to that event." It is one of the finest illustrations in the book, and it will enable our readers to judge of the accuracy and faithful renderings of the originals by Mr. W. S. Weatherley, who has kindly placed them at our disposal. We may observe, *en passant*, in relation to this work—though not without some regret—that the archway at the end of nave has been lately closed by an elaborate reredos, from the design of Messrs. Slater and Ingelow, and that a reredos is in progress for the Lady Chapel, the execution of which has been entrusted to Messrs. Farnner and Brindley.

Our other photo-lithos illustrate the little Church of St. Julien le Pauvre, Paris, now the chapel of the Hôtel Dieu. This work Sir Gilbert Scott gives as one of a typical series of Medieval remains of great value. Speaking of this example in his eighth lecture he observes, "The choir and its aisles form a perfect work on a very small scale, in the Transitional style, with Byzantine foliage." The church is but little known, but is well worthy of attention. It shows how mistaken is the idea that the Early French style is not suited to small buildings. The clear width of the side bays is actually under 4ft., and the other dimensions in proportion, yet the whole not only has not a miniature but has a decidedly dignified air, while its details offer considerable varieties, even the two apsidal chapels being wholly different in their design and plan. What remains of the nave and the fragments of the fine western portal are good specimens of the succeeding style. Our illustrations show views of choir, the south aisle, and south chapel, the drawings of which have been made by Mr. Weatherley, from Sir Gilbert Scott's own sketches, the plan being from his measured dimensions.

THE HOLBORN UNION INFIRMARY, HIGHGATE.

A FULL description of this building will be found in an article on p. 269.

ART UNION FOR LONDON—NEW PREMISES, 112, STRAND.

THE week before last we published the plans and general elevation of this new building, and last week we gave a sheet of details of the upper portion of the front. To-day some further details are given, illustrating the principal story, or first-floor facade. The balustrade shown in the upper part of our plate to-day is as originally intended; the executed work at this point is more correctly given in our sheet of last week. In other respects our illustration published herewith represents the parts as now finished. A full description of the building will be found with the plans above referred to. Shortly, we hope to give enlarged details of the earving, which is exceptionally good. Professor E. M. Barry, R.A., is the architect. The execution of the whole of the scagliola marble columns and pilasters has been placed by the architect in the hands of Messrs. Bellman and Ivey, of Wigmore-street, W.

GROUP OF THREE COTTAGES.—"BUILDING NEWS" DESIGNING CLUB.

THE design by "Yesram" for a group of three cottages, which we publish to-day, was placed first in the competition, though other designs ran "Yesram" rather close in the race. The plan, according to our conditions, provides for one cottage to have six rooms, and two cottages with four rooms each, an arrangement frequently required, though perhaps not so often conveniently planned. "Yesram" estimates the cost of his plan at 6d. per foot cube, giving a price of £582 for the main block, and £106 for the outbuildings, making a total of £688.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT the special meeting held on Monday last, the President announced that the Prince of Wales had consented to dine with the members on the 26th of April.

It was next announced that the Council had determined to recommend for the award of the Royal Gold Medal the name of Count Melchior de Vögne, whose archaeological works, according to Mr. James Fergusson, "add more to the knowledge of the architecture and archaeology of Syria than any that have ever been published."

The following recommendations of the Council respecting the award of medals and prizes for the current session were communicated to the meeting by the President:—

Soane Medallion:—Four sets of drawings submitted under the mottoes respectively of "Acropolis," "Classic," "I strive," and "Spes"; Soane Medallion, with the sum of £50, awarded to the author of the drawings distinguished by the motto "I strive," William R. Lethaby (age 22), Eberly Lawn, Barnstable.

Sir William Tite's Prize of £30:—Six sets of drawings submitted under the mottoes respectively of "Acanthus," "Antipodes," "Green Margins," "Italiano," "Patience et Spes," and "Spes"; prize awarded to the author of the drawings submitted under the motto "Green Margins," C. E. Sayer, 17, Soho-square, W.; Medal of Merit awarded to the author of the drawing distinguished by the motto "Patience et Spes," Herbert Alexander Pelly, Morden, near Mitcham, Surrey; Certificate of Honourable Mention awarded to the author of the drawings distinguished by the motto "Acanthus," Frederic Edwards, Queen's Chambers, John Dalton-street, Manchester. Grissell Gold Medal.—Four sets of drawings submitted for this Medal, under the mottoes respectively of "Alpha," "Between Whiles," "Cruz," and "Dulce Domum"; Medal awarded to the author of the drawings submitted under the motto "Dulce Domum," G. H. Blagrove, 84, Southampton-row, W.C. Institute Silver Medal (with five guineas): Drawings.—Five sets of drawings submitted, under the mottoes respectively of "Architecture," "Ars longa," "If I don't get it I'll try till I do," "Labor," and "Thorn"; Medal, with the sum of five guineas, awarded to the author of the drawings distinguished by the motto "Labor," Frederick Pinches, 359, Strand, W.C. Certificate of Honourable Mention awarded to the author of the drawings distinguished by the motto "Architecture," Sydney Vacher, 7, Stanley-crescent, Kensington Park, W.

Institute Silver Medal: Essays.—The President announced that not a single essay had been sent in, and that last year the same thing had occurred. The competition was open to all members of the profession without limitation as to age, and the subject of the essay set for the current session was

"The Architecture of London in the 16th, 17th, and 18th Centuries." It was much to be regretted that so little interest seemed to be taken by the younger men in the literature of their art. Prof. Kerr, *Fellow*, suggested whether something could not be done to stimulate the production of essays, in which they had been lamentably deficient. He only recollected one really good essay that had been sent in, but that did not get a prize, though he and Professor Lewis voted in favour of it. He thought a fair amount of money prize would stimulate work in that direction. To prepare an essay on the architecture of London in the 16th, 17th, and 18th centuries was a work which merited a greater acknowledgment than a medal of merit. Any number of medals of merit might be granted. There were young members of the Institute who could write well, as was evident from the columns of the BUILDING NEWS. When he (the Professor) was on the Council—if one was at liberty to say, after the changes of 1887, that one had ever been on the Council—the idea was entertained that some stimulus might be given for the production of essays of the high character which prevailed in the Institution of Civil Engineers, which were for the most part productions of high merit. He would suggest that the Council should take the question of the essays into their consideration. The discussion closed with an assurance from the President that the Council would give the matter their serious consideration.

COMPETITION.

BUSHEY.—The Building Committee have selected the designs submitted by Messrs. Coe and Robinson, in competition for the erection of a new church at Bushey, Herts. Five designs were submitted and noticed by us on p. 237.

CHIPS.

The Board of Trade have reported to the House of Commons that a provisional order has been made sanctioning the construction of a new pier at Ramsgate, commencing near the entrance to the "Etablissement," and extending seaward for about 600ft.; also for a pier at Westgate, extending from the cliff seaward for about 1,000 yards; also that provisional orders have been, or will be, made for a floating-dock at Penzance, and for piers, quays, sea-walls, or other harbour works at Cromarty, Fortrose, Lybster, St. Anne's (Lytham), Skegness, Strachur (Loch Fyne), Totland Bay, and Whitehall, Stronsay.

Mr. Hodgson, a builder, of Malton, lost his life on Saturday through his own imprudence. His workmen had been turning an arch over a wine-cellar, and completed the work on Friday night. On Saturday morning Mr. Hodgson ordered them to remove the centring and supports, but they refused, considering that the masonry was not set. He then proceeded to knock away the woodwork himself, when the mass fell upon him, breaking his neck.

It is proposed to erect a new church in the north-east district of Penzance, in the Penrose-terrace. The idea is to erect a church for 600 persons at a cost of about £5,000, and large subscriptions have been promised towards this sum.

The Stapleford School Board are about to build new schools in three departments for 330 children, from the designs of Mr. R. C. Sutton, architect, of Nottingham.

The museum buildings at Elgin are about to be enlarged from plans prepared by Mr. George Melven, architect, of that city.

The Romford School Board have approved plans prepared by Mr. Hudson, their architect, for new class-rooms.

The district of Attofts, in the West Riding of Yorkshire, is about to be supplied with water in accordance with a scheme proposed by Mr. Lumley, C.E., of Wakefield.

The Town Council of Bradford, Yorkshire, have appointed Mr. J. H. Cox as borough surveyor at a salary of £500 a year.

Dr. Page, Professor of Geology at Durham University, and a voluminous writer on geology and the physical sciences, died at his residence, Newcastle-on-Tyne, on Sunday, aged 64.

Mr. John Sutcliffe has been appointed architect by the Todmorden School Board for new schools about to be erected at Vale, near the town.

The Croydon Local Board have declined an offer from the West Kent Sewerage Board to grant the town an outfall through their sewers on payment of 8d. in the pound on the rateable value of the entire district, and at the same meeting decided to proceed with the drainage of Coulsdon.

A new line of railway in South Nottinghamshire, and constructed for the Great Northern and London and North Western Railway Companies, is about to be opened for traffic. Messrs. Logan and Henningway were the contractors.

ROYAL ACADEMY LECTURES ON
ARCHITECTURE.THIRD PERIOD OF RENAISSANCE.—PALLADIO AND
VIGNOLA.

PROFESSOR E. M. BARRY brought his series of lectures to the students of the Academy to a close, for the present session, on Monday evening, by an address in which he reviewed the final development and decay of the Italian Renaissance, and, having glanced at the development of Italian architecture to which this year's course of lectures has been devoted, the question of the possible further revival and growth of the Renaissance was considered.

Thus far, said the lecturer, we have traced the progress of the restored taste for antique architecture in Italy up to the time of Bramante and Sansovino. This has been called the Golden Age of the movement; and if the latter be divided into three periods, we shall find it ranking as the second, or middle stage. The first period was Transitional, a time of fusion, when the architecture was subordinated to the decoration. The second period carried the revival of old forms a step further, and broke more decidedly with Gothic precedents. Its architects studied Roman principles of construction as well as Roman types of design. Brunelleschi's dome at Florence was the first fruit of the process, which led to the triumph of Michael Angelo at St. Peter's. Bramante and Sansovino applied Roman architecture to modern wants, with a success never since exceeded. Not only did they adopt the columns, pilasters, and entablatures of the Roman orders, but they sought also in the details of their works to resuscitate the old Classic spirit. Their time has, therefore, been appropriately called the Roman period of the Renaissance. But Bramante did not live to perfect his plans for St. Peter's, and the completion of this great work by Michael Angelo marks the time when the second period of Roman vigour was giving place to a more formal accuracy and a pedantic precision. Simplicity of general design, with a colossal largeness of detail, were the principles which suited the impatient nature of Michael Angelo; and they are illustrated by his abandonment of Bramante's plan in favour of a Greek cross, and by the introduction of a huge order, with the consequent exaggeration of subsidiary details, which detract so greatly from the effect and apparent size of the building, as we now see it. It was probably a reaction against an exaggeration only tolerable when directed by genius, which led to the colder and more tranquil designs of the later Renaissance. Architecture, which, at the revival of letters, had followed scholarship, still felt the same influence. The first burst of enthusiasm had been succeeded by knowledge; and knowledge was now giving rise to a critical pedantry. False quantities were as much condemned in the architecture as in the poetry of the day. The effects of a spirit of inquiry were visible, not in art alone, but also in religion and manners. The trustful spirit of olden days had given place to a disposition to touch, taste, and handle. When the canons of taste in architecture had been established, no appeal could be allowed. The instinctive and undisciplined aspirations of the many were to be repressed by the classical fastidiousness of the cultured few, who, on their part, were bound to be able to produce, when challenged, chapter and verse for their decisions. The problem to be solved was to recall the past,—to ignore the present,—to bring back the dead to life. Can we wonder if the later Renaissance architect failed at so hopeless a task? Nevertheless, we too have our own revivals, and perhaps may even now be told, "*De te fabula narratur*."

The application of the spirit pervading society at this time to architectural design was chiefly illustrated by the works of Palladio, of Vicenza. He gave, indeed, a name to the architecture which he used, and we have not ceased to speak of the Palladian style, although the term has come to be used with some inaccuracy and much elasticity of meaning. By "Palladian architecture," it is not generally meant to refer to the architectural forms which Palladio himself actually used, but rather to Italian architecture generally. Palladio's school referred every detail to precedent, and considered that the limits of invention had been reached. Vitruvius had described the edifices of the Augustan age, and his writings were now eagerly studied as a very gospel of architecture. The proportions he laid down, and the precepts he

inculcated, were to dictate to architects for all time the principles on which alone their art must be based. Palladio's principal works are to be found at Vicenza, of which place he was a native. His best design was certainly the arcades of the Town-hall—a building which, notwithstanding admitted defects, has a charming effect of proportion, and of light and shade. A peculiarity of his designs is found in a weak treatment of the angles. Notwithstanding this defect, however, Palladio's designs are usually well-studied. The fame he obtained was chiefly owing to his eye for proportion, while the distribution of the parts give a pleasing character to his buildings generally. Vignola and Scamozzi are generally ranked with Palladio as members of the same school, and its pedantry is more to be attributed to their followers than to those distinguished architects themselves. Still it is evident that if they had regarded the arbitrary proportions of the Classic orders with less reverence, their talents might have carried the Renaissance to a further and more successful development. This, unfortunately, was not the case, and the rules which were to achieve perfection served to stifle art. The buildings of the post-Palladian school were incapable of exciting enthusiasm, and can at best be regarded as careful academic studies. As time went on, men spurned the fetters sought to be imposed upon them, and rushed into the excesses of exaggerated detail, known by the name of "Rococo." The Renaissance was nothing if not progressive, and the ultra-classic formality which now reigned supreme was the herald of decay. We may perhaps learn from this the truth that no selection of a past style of art, and no mere careful reproduction of its details, will ultimately satisfy a society which has little in common with those for whose needs such architecture was originally invented and used.

Vignola's greatest work was the noble Palace of Caprarola, near Rome, a building simple in plan, and so treated as to present a castellated, rather than a domestic, aspect. The design is graceful, with a double order, and a well-proportioned arcade to the entrance-front. The weakness of the angles, noticed in Palladio's designs, is here avoided. The plan is a pentagon, with a circular court within, and was evidently controlled by military considerations. The building is a fine specimen of Vignola's talents, and, with a few additions, would be a grand architectural monument. The pentagonal form, however, is not agreeable, as the angles caused by it present an awkward appearance, and the castellated treatment of the plan is not adequately carried out in the external design. The elevation of each side of the pentagon is that of a palace, and in the details the military character is also together absent. The latter might have been preserved, and the place greatly strengthened, if the angles of the pentagon had been marked by towers, projecting so as to command the flanks, and carried up, so as to break the monotonous line of roof. If this had been done, and the central circular court covered by a domed roof, the building might have been rendered far more effective architecturally than at present. Vignola was more Palladian than Palladio in his exact reference to ancient Classical rules. His treatise on the Five Orders aims at the authority of a text-book, and is still, in that sense, deserving of study. He did not give the proportions of any actually existing details, but by a principle of selection, he sought perfection in the survival of the fittest, and thought to weld the whole together into one harmonious system. He was invited by Philip II. of Spain to superintend the erection of the Escorial, for which many designs had been obtained from various architects, but declined the invitation. On the death of Michael Angelo he became for a short time the architect of St. Peter's, in which capacity he designed and erected the two lateral cupolas of the building. His works rank on equal terms with those of Palladio; and, indeed, in elegance of detail may be held to surpass them. He had no inconsiderable talent as a painter, particularly of perspective, and used to say that a study of the latter science had led him to adopt architecture as his profession. Vignola visited France, and remained there about two years, which probably accounts for the tradition that he designed the Chateau de Chambord. This could scarcely, however, have been the case, as the building was commenced before the time of his visit, and certainly does not accord with his usual principles of design.

It is more possible that he had something to do with the designing of the palace at Fontainebleau; its general appearance is more consistent with Vignola's architectural principles, although the details are not to be compared with those of his best works in Italy. At the time of Vignola's death in 1573, Palladio was nearly at the end of his career; but his traditions were, for a time, upheld by Scamozzi, a young man then rising into fame. He, too, was a native of Vicenza. He settled in Venice, and took up the work of Sansovino and others. He continued the design of the Library round the south side of the Piazza of St. Mark, adding a third order, and altering the deep frieze and cornice of Sansovino. These were not improvements, and his work wants dignity and interest. Like other architects of his time, he also turned his attention to military engineering, and laid out the fortress of Palma, near Friuli. In this he used the forms of the Renaissance, and gave them a peculiarity of character, by the use of simple rustication. For the massive walls of fortifications such a treatment sufficed; in such cases delicate mouldings, and such details, would have been out of place and unnecessary; but for the gateways, the architects of the Renaissance adopted somewhat more elaborate designs. The device of rustication was freely employed by the later Renaissance architects, but always in subordination to the general effect, and not after the lavish fashion of the old Florentine school. The Palladian architects usually rusticated portions of their buildings only, preferring such parts as seemed to require additional strength, as the ground or basement stories. Vignola did this at Caprarola, and he also carried up rusticated quoins, at the angles of the projections of the upper story. This system of marking the courses has been generally adopted in revived Renaissance architecture in all countries. Wren used it at St. Paul's, and Inigo Jones at Whitehall, and the characteristic Water-gate of the latter in the Savoy is a pleasing specimen of the military type, similar to that adopted by San Michele. In Italy, the use, in Mediaeval times, of voussiors to the arches, of different colours, had an effect nearly related to rustication; and a similar method was common in Byzantine and Eastern work. Of late years, it has been customary to condemn rustication, and it is no doubt liable to abuse. It has, however, when used to emphasise actual masonry joints, an appropriateness in many situations, and may be used by an architect so as to give scale to his work, and to modify the monotonous effect of too much plain surface. An example may be seen at Bridge-water House, particularly in the part facing the Green Park. The rustication of this front is applied to the ground floor only, over the surface of the wall, and at the angles of the projections above, and we feel that it is both reasonable and effective.

With Palladio, Vignola, and their followers, we terminate our examination of the architectural Renaissance of Italy. It has been said that Vignola, by his treatise on Proportions, and Palladio, by his prescription of strict regulations, would have made of architecture an exact science, in which precise knowledge might render success certain. This is, however, very far from fair, as is proved by the examination of Palladio's own works. True, he aimed at precision in his application of the orders; but there is much variety in his different designs, and his details were usually refined. His palaces at Vicenza have served as models to the architects of most civilised countries, and they have survived the attacks of unsparing criticism. We realise more fully the merits of Palladio when we contrast his measured and studied compositions with the reckless and bizarre specimens of tricky designs which followed in the fantastic reaction of later days. In Palladio's buildings we find occasionally the mistake of enormous details misapplied, as at the Valmarina Palace; but in other instances an order was used to each story, with details properly subordinated. Propriety of detail and proportion had given a fame to Palladio which would not have been gained by the picturesqueness of his designs, or the fertility of his inventive genius. His style has influenced the revival of Classical architecture throughout modern Europe, including this country. Wren, Jones, Vanbrugh, with many others, have followed more or less Palladian precedents, and Somerset House, by Sir W. Chambers, is just such a building as might have been erected by Palladio or Vignola.

The use of Classical architecture is still common, although its progress has been checked by the Gothic Revival. The architecture evolved from the principles of Ancient Greece and Rome has been denounced, we know, as inadmissible, and stigmatised as Pagan. An active spirit of theological revival has led to the restoration of our churches in the old Gothic styles in which they were erected. Eloquence of critical disquisition has occupied itself with declaring the Renaissance an unholy thing; an evil spirit to be exorcised; a fault to be purged by a return to the straighter and better ways of Mediaevalism. The choice of a style might almost seem to be a question of morality, rather than of architecture. In deciding such a question, it must be remembered that a complete revival cannot but be impossible, whether of the architecture or of the spirit of the past. The world moves onward while we argue, and each generation has its own requirements. We may copy Greek temples, but we cannot be as the Greeks were, or think their thoughts. Neither can we revive the Mediaeval spirit by clothing our architecture in a Gothic garb. It cannot be admitted that limits are to be placed to the adoption by mankind of the extension of their powers by the increase of knowledge. To be for ever protesting against the things of to-day is a profitless, as well as an easy task. Some critics think the present always bad; their artists always failures; their own country always wrong. This is not a spirit which is likely to lead to healthy development in architecture. If we cannot recall the past, it does not follow that we may not be gainers by its experience, and thus take a new departure. We may fairly profit by its achievements, and draw precedents from its treasures. Hence we have the responsibility of choice of style placed upon us. It is, therefore, not reasonable that we should be forced to select one type, and use it for all purposes, merely because our predecessors did so, in ignorance of any other. Still less can it be contended, that we are not at liberty to avail ourselves of successive phases of the same style, because such a course is inconsistent with chronological accuracy. It is not the business of the modern architect to erect buildings which may deceive his successors as to the date of their execution.

We claim the liberty to select different architectural types for different things: thus, to some of us, the Gothic style may appear the most suited for churches and sacred buildings; and the Italian more appropriate to secular work. The first of these decisions has already been accepted, for the present, at least, in this country, and Gothic architecture has been practically adopted for church building. But while recognising the existing preference for Mediaeval architecture for ecclesiastical works, it cannot be allowed that the Classical style should of necessity be neglected. The Palladian school of architects had a definite intention, which was to design a modern style, that should be based upon the architecture of the Romans. Whatever merit may be assigned to their works, they certainly produced buildings unlike any that had previously existed. They copied, or intended to copy, literally, the details of the orders; but neither Palladio's arcades or Sansovino's palaces are direct reproductions of actual buildings. They, at least, succeeded in applying ancient art to modern use, in a manner which has been imitated ever since. We have had, in this country, many tastes, and various revivals; but through them all, the Palladian or Italian manner of Wren and Inigo Jones has held its ground, and something of a reaction towards it has lately appeared in unexpected quarters. If it be said that such architecture is unsuited to our climate, it may be pointed out that it has been generally adopted in climates not much unlike our own, and these who have lived in one of the solid houses, of simple outline, which the architects of the English Renaissance have left to us, would not care to change, to the so-called picturesque creations of Modern Gothic, with their voluntary carelessness of plan, and the maximum of surface of external walls and roofs. In modern domestic work we must often welcome novelties, which we do not desire to see in our churches. We may, in the latter case, be content to rest satisfied with piers which are obstructive, and arches of unnecessarily contracted span, while, in secular buildings, convenience must rule, and science be invoked to aid us to overcome difficulties, and economise space. It is not wise of the architect to leave such matters to the engineer. He must use his art intelli-

gently, being ever ready to adapt it to all reasonable requirements, and the Renaissance, as a modern style, will apparently have less difficulty in accepting this position than the more stern and stiffer types of Mediaeval art. For grand architectural effect, moreover, and for the convenience of a spacious interior, Classic architecture possesses the dome, if not absolutely, at least more fully, than any other style. Those accustomed to visit St. Paul's, cannot accept, unreservedly, the popular doctrine that our churches must of necessity be Gothic. A calm review of the history of the Renaissance, and of the circumstances which led to it, conducts us, said Professor Barry, to the conclusion that the movement is not yet over. The Classical tastes which gave to it the first impulse still exist among us, and are likely to continue. An architecture which can give us solidity and magnificence; which can adapt itself to purposes of utility, and assimilate progressive scientific construction; which unites elegance of proportion with refinement of detail; and which welcomes the best efforts of the painter and the sculptor in a loving combination of art, cannot be easily banished from the modern practice of the civilised world.

THE ART DECORATION OF THE STAGE.

MR. Walter J. Allen delivered a lecture on this subject before the members of the Society for the Fine Arts, at 9, Conduit-street, W., on Thursday evening. The Marquis Townshend occupied the chair.

In his opening remarks Mr. Allen said his object was to contemplate the art decoration of the stage as it now is, and in order to do that it was necessary to take a retrospect of its history. In Queen Elizabeth's time the decoration of the stage was but a poor affair; the only accessories consisted of hangings of tapestry, and the floor was strewn with rushes. The Globe Theatre itself, according to Taylor, the water-poet, had a "thatched hide." Most of the halls of the different Inns of Court have been the scenes of dramatic success. The stage merely consisted of a platform, and the entrances and exits were by steps at each end, and in sight of the audience. There is no doubt the side scenes of a modern theatre help the illusion greatly, breaking, as they do, the actor away from the spectators, and leaving the impression of his art on the minds of his audience. The art decoration of the stage must have advanced rapidly, for the Globe Theatre was destroyed in 1613, from the circumstance that Shakespeare's play of Henry VIII. was played on the boards so completely, that on the arrival of the King to visit Cardinal Wolsey at York Palace, the supernumeraries fired real cannon, and the wadding being also real, alighted on the aforesaid thatched hide and burnt down the theatre in a most realistic manner. In a letter preserved in the British Museum, the writer, a nobleman, says, that the details of the dressing of the play were so complete, that the representatives of the Knights of the Garter wore all the insignia of the order, and were quite correct as to detail. The rebuilt Globe was closed with all others in 1642, by order of Parliament. The Restoration marks a great era in the history of the stage—a change both for good and evil. The decorations must have advanced in quality and have been greatly appreciated. Pepys was told by Pettigrew that he had "greatly improved the stage from the time when there was nothing but rushes on the ground, and everything mean." The rushes were succeeded by matting; for tragedy, black cloth hangings; and then came green cloth for the floor, which, to some extent, is still used. In Queen Anne's time the decoration must have been curious, for Booth, in "Cato," was identified by the line in Pope, "with flowing wig and lacquered chair." Fancy the stern Roman in a Ramillies wig and a chair of the Rococo sort! Little need be said about the progress of decoration during the last century. We look with wonder on the portraits of the great actors of the close of the century; upon Maebeth, arrayed in scarlet coat, blue facings, powdered wig, jack boots and spurs; and Hamlet, in black dress. Canaletti supplied the scenery for His Majesty's Theatre in the Haymarket when George III. was King, as did also Paul de Letherbourg. The scenery in those days depended more on the artist than on either the property man or the carpenter; but in the pantomime most gorgeous scenery was pro-

vided, chiefly by the latter personages. Coming to more recent days, to the late Madam Vestris must be given great praise for the service rendered by her wonderful taste and judgment, though he suspected that in many of her graceful productions the veteran Planche had much to do. But the revivals of the great tragedian William Charles Maeready must be very vivid in the memories of many yet living. The arrangement of the Vineyard scene in Handel's opera of "Acis and Galatea" was perfect. The scenery was supplied by these giants in art, Stanfield and Robers, who have probably never been equalled since. Maeready brought forward both those artists, Clarkson Stanfield and David Roberts, who elevated scene-painting to an art, and who made it a splendid school for landscape painters. Among their not unworthy successors might be mentioned William Beverley, William Calcott, whose scenery at the Lyceum under the management of Madame Celeste was perfect, and Hawes Craven, who is at the Lyceum setting an example of true art. At the Strand Theatre, where the stage is very limited, the scene-painter, H. P. Hall, manages to secure an effect of space which shows a thorough knowledge of his art. To the late Samuel Phelps belongs the honour of proving that the stage can be made a great teacher. He was the favorite of William Charles Maeready, and will be remembered for having raised Sadler's Wells Theatre from a most degraded condition to a high position. Phelps thoroughly understood the principles of decoration. The scenery was always perfect; never too glaring, it was an admirable background to the wonderful acting to be seen before it. The dresses were archaeologically correct, and in perfect harmony. Reference must be made to the Chamber scene in "Hamlet" for excellence of setting up. The walls of the room appeared solid rough stone, the small windows slightly tinged with stained glass, and the decorations most appropriate. Around the room were portraits in rough tapestry of the kings of Denmark, and behind the one representing the portrait of the reigning king, Polonius hid himself. On the Queen crying for help, Hamlet drove his sword through the arras upon which was represented his father's murderer; and that ghost was caused to appear by the device of the unfolding of the tapestry portrait of Hamlet's father, and the ghostly replica of that portrait appeared moving and speaking. Equally great were the revivals of the old comedies, produced under the direction of Phelps, which were as perfect as could be done. Contemporary with Phelps was Charles Kean, who took the Princess Theatre, and there produced a series of Shakesperian revivals which for magnificence were never surpassed. The revivals were the talk of the town, but the art decoration was woefully overdone. The interminable delays between the acts, the time taken to work the different scenes, and the monotony of splendour all combined to break the interest of the play itself, and the gorgeousness of the frame entirely killed the picture. The drama, as Douglas Jerrold puts it was elevated—but on to a clothes-peg. Except this over-lavishness, Kean was in every respect a true artist, and trained a good school of actors. Fechter, the French actor, showed great taste and learning in his arrangement of the stage. At the Lyceum Theatre, when manager, he went one day into the wardrobe, and taking up a dress for a piece then being played, remarked that it was very pretty but went too far, as there was a space of about 150 years in one costume, and with a pencil and paper he drew the dress perfectly correct. He introduced great picturesqueness and novelty into the scenery, and abolished the dreadful carpenter's flats closing together with a crack. The author referred to the present revival of Shakesperian plays by Mr. Irving, and incidentally argued in favour of the abolition of the supernumerary, relating many amusing instances of his marplot abilities. In Irving's revivals, attention was called to the great knowledge of the laws of light and shade displayed by the scene-painter, and in the wonderful way in which the lighting arrangements are carried out. By the judicious lowering of lights in some parts and raising them in others, the production of accidental effect is most successfully obtained. The change in the first act of "Hamlet," from the platform of the Castle to the interior, is one of the most perfect improvements in this important act. Instead of the sudden splitting of two wings, including sometimes a great exhibition of very dirty fingers belonging to the scene-shifters, the stage is suddenly darkened, a slight noise is heard, a few flitting forms may be

observed on the stage, suddenly the lights are raised, showing a palace interior as of solid stone, the floors covered with skins of deer, and all the furnishing in perfect harmony. The dresses in "Hamlet" have never been excelled. The scenery of a play ought to be subordinate and subservient to the acting, and to help in the harmony necessary for the general effect. Theatrical managers could, it was urged, at a much less cost than is now incurred, obtain a far better result, if in every theatre could be appointed an artist who, having a keen appreciation of art in its various phases, and working cordially with the principal performers, could direct the action of the piece completely, so that the grouping be arranged that the stage picture should look unstudied, and help the action of the play. One of the best stage managers of our time was the late Augustus Harris. At dress rehearsals he would, from the centre of the pit or the dress circle, direct the grouping of the supernumeraries with great judgment. He seemed instinctively to arrange them so that the composition, the colour, and the light and shade of the living stage picture were most effective. The more careful art is the more carefully it is hidden, and it would be well if, in the future, that wonderful production, the supernumerary, could be missing. Some time since, a comedy was produced at the Haymarket Theatre which had a wonderful run. One of our most popular comedians was "made up" as a very fair man. His costume was light brown, the back scene representing a Scotch moor, was highly charged with bright yellows, rich browns, and crimsons. The result was, that from the pit the actor was completely lost. Had he worn a black hat or even a white waistcoat the fault would have been corrected to some extent. Reference was here made to the admirable setting of "Plevna" and the "Battle of Trafalgar" at the Canterbury, under the superintendence of Mr. Villiers, the energetic war correspondent of the *Graphic*. It could not be denied that in some theatres the art decorations had improved greatly during the last twenty years, but in others it has gone on striding at such a pace that the decoration is all one had to see when visiting a theatre. The realism of the furniture and decorations is so great that the only artificial thing in the entertainment is the acting. At one of the largest theatres in London a great sum of money has often been spent to make one or two particular scenes excessively gorgeous and all the rest are as mean as possible, and often the costumes are anachronisms. It will be a great thing for English art when all the professions are more homogeneous, when there is more sympathy than there is now between dramatic, musical, and pictorial art. He trusted the narrow-minded prejudice would be swept away, and that these professions would soon rank equally with those of Law, Divinity, and Physics.

Mr. CAVE THOMAS, in proposing a vote of thanks to Mr. Allen, urged the importance of subordinating all scenic decorations to the acting. If one were reading one of Shakespeare's plays he could grasp the plot and see in his mind every detail without an atom of scenery, and so if the attention were fixed on the play the stage accessories were of comparatively little moment. The human intellect could not comprehend completely more than one subject at a time. The words being spoken were the chief thing for which the audience listened, and stage managers made a mistake when they allowed music, dresses, and scenery to be other than secondary to these. The first requirement of the drama was good acting.

At the meeting of the Darlaston Local Board on Tuesday, the Public Buildings Committee recommended the erection of public offices, to include the necessary rooms for the clerk, surveyor, collector, and inspector of nuisances, and Board-room; and also a Free Library, Reference Library, Reading-room, with all the necessary rooms and offices for the conduct of the business of the library. The surveyor reported that he had prepared directions for architects, and the total cost of the erections was not to exceed £1,500, and the successful competing architect would be engaged to carry out the works at the rate of 5 per cent. on the amount of the contract.

In our description of Messrs. Lindsay Bros.' warehouse at Belfast, in our issue of the 28th ult., we omitted to mention that the premises had been fitted throughout with the Patent Balance Weight Revolving Shutters, of Messrs. Salmon, Barnes and Co., of Ulverston, Lancashire.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—At a meeting of this association, on Tuesday evening, at Queen's College, Mr. J. Roddis delivered a lecture on "Pre-Gothic Ornament in Europe, and the Treatment of Terra-Cotta." The lecture was illustrated by a large number of cartoons. Mr. Roddis also exhibited some specimens of terra-cotta made from his own models by Messrs. Doudton and Co., of Lambeth, for the new College of St. Bede, at Manchester.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The sixth meeting of the Session was held last Wednesday week, the Rev. S. M. Mayhew in the chair. The Rev. Prebendary Sir B. Baker, exhibited drawings of a singular Roman vessel of brown earthenware found by Col. Akers near Chatham. It is of unique form, having apertures at both ends designed for raising and retaining water by suction, after the manner of the later mediæval watering-pots. Mr. C. Brent, F.S.A., described a forged inscription on marble from a celebrated collection, and which was found, as believed until now, in Cannon-street. Mr. Loftus Brock, F.S.A., exhibited a beautiful specimen of Egyptian glass recently found in Cyprus. It is a small phial covered with wavy lines of black worked in the material. The Chairman exhibited a fine collection of objects of Spanish glass, others from Venice, and a beautiful specimen—a mask with a background inlaid as if with silver. These were described at length by Mr. Syer Cuning, F.S.A. (Scott.). Mr. Earle Way described a collection of articles found in excavations at Princes-street, and Mr. Compton exhibited some old family plate. The first paper was by Dr. Pléné, F.S.A., descriptive of the Cave of the Oracle of Delphi. The second paper was descriptive of the little-known monument at Gunnersfield, near Shap. These are two irregular concentric circles of small stones, of sepulchral character it is supposed, but there is no trace of the usual covering-mound.

GLASGOW ARCHITECTURAL ASSOCIATION.—The first annual meeting of this association was held on the evening of Friday last, when the secretary's report and treasurer's statement were read and adopted. The report shows that a considerable amount of good work has been gone through during the first year; the essays read were on subjects of a practical nature, which have proved highly beneficial to those who have attended and taken part in the discussions which followed them. An exhibition of drawings took place during the year, and was visited by many who take an interest in architectural drawings. The treasurer's statement shows a surplus after clearing off all debts. The latter part of the evening was occupied in the election of office-bearers and hon. president. The gentlemen elected for ensuing year are:—Honorary President—James Sellars, jun., Esq., I.A.; President—Mr. James B. Stewart; Vice-President—Mr. Ambrose J. Russell; Treasurer—Mr. James Lindsay; Secretary—Mr. Alexander Rae.

LEEDS ARCHITECTURAL ASSOCIATION.—At a meeting of this society, held on Thursday week, a paper, entitled "House Planning," was read by Mr. Henry Walker, one of the vice-presidents of the association. Mr. Walker, in his opening remarks, said that he intended confining himself to a description of the points to be attended to in the arrangement of a suburban house, to cost from £5,000 to £8,000, and that his notes would be found to apply in a modified form to town houses as well. Diagrams were exhibited to explain the suggested arrangements. Before proceeding to make sketch plans he advised all architects first to see the site and thoroughly to discuss the details of the plan with the client and his wife. Mr. Walker strongly condemned irregularity of plan for the sake of mere architectural display, and quoted from the works of Sir Gilbert Scott and Professor Kerr in support of this. He recommended simplicity and compactness of plan as far as the proper arrangement of the rooms would permit, and then proceeded to explain the qualities of a well-planned house and the best kind of site to select, pointing out the position the house, out-offices, stable buildings, kitchen garden, &c., should occupy on it, and dwelt in detail on the question of aspect, prospect, and the approaches. He then entered minutely into the arrangement of the house and kitchen offices, taking each room separately, and

giving reasons why they should come in certain positions for convenience, as well as with regard to aspect, &c.

PARLIAMENTARY NOTES.

RIVER CONSERVANCY.—In the House of Lords last Friday, the Duke of Richmond and Gordon presented a Conservancy Bill. Having stated that legislation on this subject dated as far back as the reign of Henry III., and that the Statute of Sewers, passed in the reign of Henry VIII., as amended by other Acts, was still in operation for the conservancy of rivers, his Grace referred to the report of a committee their Lordships' House appointed in 1877 to show that the existing system of conservancy was very defective. Under the Bill, the first reading of which he now proposed, any ten or more landowners or any Sanitary Authority or Conservancy Board in a district would be able to supply to the Local Government Board for the establishment of a new Conservancy Board. The Local Government Board would hold an inquiry and hear any objections that might be urged against the proposal. It might then, if it so thought fit, issue a provisional order for the establishment of the Conservancy Board; but before doing so it might require an undertaking from the promoters that they would, if necessary, appear before Parliament to sustain the provisional order. One-third of the members of a Conservancy Board under the Bill would be life members and the rest members elected by the Sanitary Authority. All of the former class of members and one-half of the latter must be landowners. The Board would have power to tax the whole district, to grant exemptions from taxation where lands were injured, and to impose an improvement rate where lands were benefited by conservancy operations. Tenants would be entitled to deduct from their rent one half of the rate paid by them to the Conservancy Board. Such were the main provisions of the Bill, and he believed they were well calculated to effect the object for which they were intended. After a few words of approval by Lord Ripon and of inquiry by the Duke of Somerset, the Bill was read a first time.

THAMES VALLEY SEWERAGE BILL.—In the House of Commons there was a long discussion on the Lower Thames Valley Main Sewerage Board Bill, the object of which is to dispose of the sewage of the district below Staines by means of a large sewage farm. Its rejection was moved by Mr. Isaac, who pointed out that it would injuriously affect the comfort and the property of inhabitants, who would have no *locus standi* before the Select Committee, and Sir W. Barttelot, Mr. Serjeant Spinks, Mr. Herschell, and Mr. Raikes also spoke against it. On the other hand, Sir A. Lusk, Mr. Shaw-Lefevre, Lord G. Hamilton, Mr. Watney, Mr. Childers, and Mr. Selater-Booth supported the Bill, on the condition that it be referred to a hybrid committee, where all persons affected could be heard. On a division, however, the House threw out the Bill by 168 to 146.

METROPOLITAN WATER SUPPLY.—Dr. Playfair gave notice that on an early day he will call attention to the increase of zymotic disease in the metropolitan district, owing to the impurity of the water supply, and will move a resolution.

THE NATIONAL GALLERY.—Mr. Ritchie asked the First Commissioner of Works on Monday whether his attention had been called to the blistering of several of the paintings in the new rooms in the National Gallery, and whether he could state the cause, and what steps were being taken to prevent further injury. Mr. G. Noel said, During the recent severe frosts considerable difficulty was experienced in maintaining an even temperature in the large rooms in the building, and perhaps on one or two occasions the heating apparatus was rather overheated, so that the hot air admitted through the gratings might have caused the blistering alluded to; but I am informed that this is a damage to which old pictures are specially liable in all galleries, owing to the material being subject to expansion and contraction. The gratings have now been removed and placed elsewhere, and I am happy to inform my hon. friend that Mr. Burton, the director of the National Gallery, considers that the damage done to the pictures is not irreparable.

Building Intelligence.

HASTINGS.—Another stage has been reached in the Town Hall controversy, the Town Council having decided at their meeting on Friday last to proceed with the structure to be called the "Municipal Buildings." The site, as finally selected, will be on the stoneyard adjoining the Central Hotel, and will be entirely covered by the new buildings, which are to be erected from the designs of the borough surveyor. The principal front will be in Queen's-road, and will be 50ft. in length, two stories in height, and of Gothic design, with bluestone walls and freestone dressings. On the ground floor are placed a jury room and town clerk's office, each 25ft. by 18ft.; a magistrate's room, 18ft. by 18ft.; and robing room, 26ft. by 15ft. In a triangular piece of ground at the rear will be a rate-collector's office, 14ft. 6in. by 8ft. 6in.; waiting-room, 28ft. by 17ft.; and constables' day-room, 18ft. by 12ft.; and there are also a series of eight cells, with entrance from Station-road. On the principal floor are a council-chamber, 46ft. by 31ft.; mayor's parlour, 18ft. by 16ft.; committee-room, 18ft. by 29ft.; and two surveyor's offices, each 17ft. by 18ft. There are also a large police-court and policemen's living-rooms. The estimate for quantities will be at once got out. The total cost is set down at £15,000, and this for building alone, as the site belongs to the Corporation.

KEPPOCH-HILL.—New Board Schools were opened at Keploch-hill, near Glasgow, on Friday. The premises consist of a central building two stories high, with wings on either side, and a tower three stories high containing teachers' rooms. On the ground floor, in the centre, is an infants' schoolroom, 40ft. by 30ft., communicating with two initiatory rooms. On the upper floor of the centre building is a senior schoolroom, also 40ft. by 30ft., and having an open timber roof. Open fireplaces are introduced into all the rooms, but will only be used occasionally, as hot-water pipes are laid throughout the buildings. The site cost £9,646, and the expense of erection was £8,100. The schools accommodate 584 children, so that the cost per head is nearly £13 18s. Messrs. D. Thomson and Turnbull are the architects.

LAMBETH.—The chapel of Lambeth Palace, having fallen into a state of dilapidation, has recently been partially repaired and decorated, under the superintendence of Mr. J. P. Seddon. Its plan is a parallelogram of four bays, with a three-light window in each bay, and a five-light one at its eastern and western ends, the latter of which is now blocked up by the Lollards' Tower of later date. All the windows have Purbeck marble shafts, and till quite recently those on the south side were filled with masonry to about half their proper height. Most of these now, however, have been restored to their right proportions, and filled with stained glass. The windows were originally filled with stained glass by Archbishop Morton, and at Land's trial it was alleged that "he did repair the story of those windows by their like in the Mass-book." The subjects illustrated on the glass are now, as then, the types and antitypes of our Lord, showing forth, by such, the history of the world from the Creation to the Judgment. The sacra-rium has been enriched by a pavement of encaustic tiles inclosed within marble steps, with foot-pace and oak altar-table, the whole being from special designs of the architect. It is contemplated to add shortly an organ, to be placed in a chamber of the Palace abutting upon the north side of the easternmost bay of the chapel.

LISKEARD.—After having been closed for about nine months, during which the work of restoring it has been carried on, the ancient parish church of Liskeard was opened on Wednesday. With the exception of that at Bodmin, Liskeard Church is the largest in the county of Cornwall. The style is "Debased Perpendicular." The church, which is dedicated to St. Martin, Bishop of Tours, consists of a chancel, nave, north aisle, built in 1477, south aisle, erected in 1428, extreme south aisle or lady chapel, and vestry. In the course of restoration, the old organ-loft, at the west end of the nave, has been removed, and an organ chamber has been constructed near the eastern end of the north aisle. In the north porch there is a stoup, and the remains of another exist in the south porch. At the west end of the north aisle, near the tower, there is a Lychnoscope. A small

window has been inserted in the south porch, between the two lower niches for the purpose of lighting the gallery stairs. The pulpit which bears the date 1636, is tastefully ornamented with Arabesque carving, and is said to have been the handiwork of one Peter Short, once a native of Liskeard. The tower is much older than the other portions of the church. The tower stages and the arch leading into the nave are Norman. Most of the original style is preserved in the north side of the tower, but the west and south sides are patched up with a veneering of granite and plaster. A new waggon-headed roof has been put over the entire building. The roof is in pitch pine with carved bosses. There are seventeen windows in the church, of which fifteen are new ones. The whole work has been carried out by Mr. Thomas Lang, contractor and builder, of Liskeard. The contract price was £2,350, but there have been some additions, which it is expected will make the amount up to £3,000. Mr. R. Coad, of the Adelphi, London, W.C., was the architect.

METROPOLITAN BOARD OF WORKS.—At this board on Friday, a deputation from Bermondsey Vestry attended to support a memorial from that body, praying the board to reverse the decision arrived at last week, and to give their consent to the lines of tramway proposed by the South-west and Deptford Tramways Bill. It was pointed out that the action of the board, if carried out, would leave a population of 100,000 at the mercy of a railway company, and give a monopoly of the tramways in the south-eastern district of the metropolis into the hands of one company. The memorial was referred to the works committee for consideration and report. In the engineer's department, Mr. Charles Elwin was appointed in the first class of officers at a commencing salary of £240 per annum in place of Mr. R. A. Rumble, constructive draughtsman, retired. The Building Act committee reported with reference to the letter from Mr. E. L. Paraire, relative to an alleged overcharge by Mr. Kerr, district surveyor of Saint James, Westminster, in respect of certain alterations at the London Pavilion, Tichborne-street, that, in their opinion, considering the large amount and the important character of the work done to a public building, the fee charged is not an unreasonable one. With reference to the letter from Mr. E. D. Drury, district surveyor of part of Westminster, requesting opinion as to the exemption of the buildings within the Close of the Collegiate Church of St. Peter, the solicitor was authorised to express to the district surveyor the opinion that by the Amendment Act of 1878, Westminster Abbey is not exempted from the provisions of the Metropolitan Building Act of 1855, and to support any action taken by the district surveyor to enforce the law. It was referred to the works committee to consider and report on the advisability of proceeding with the Bill for the erection of the Tower Bridge.

SHEFFIELD.—The foundation stone of the new church at Sheffield, Hants, was laid May 24th, 1875, and it is hoped that in the course of the present summer it will be opened. The church was designed by Messrs. John Colson and Son, of Winchester. The general contract was taken by Messrs. Knight and Son, builders, of High-street, Wickham, and the work is now complete save the erection of the tower and spire, and some of the internal fittings. The building is in the Decorated style, and consists of a nave, south aisle, chancel, and south transept, having an entrance in the form of a priest's door out of the latter, and a fine porch at the south-west angle. Provision is made for readily adding a north aisle. In the building, local stone is used for the walling, whilst the dressings are of Bath stone. Within, coloured bricks are used considerably, with good effect. The carved work has been carried out by Mr. Harry Hems, of Exeter. The clerk of works, during the main portion of the work, was Mr. H. A. Amey.

The Commissioners of Sewers for the City of London decided last week to discontinue the electric lighting experiment on Holborn-viaduct, at the termination of the three months contract with the Société Générale, on account of the great cost. The company offered to reduce the price to 5d. per hour per lamp, but the Commissioners' declined the offer, as it would have been three and three-quarters the outlay upon gas, and the electric light was accordingly displayed for the last time on the Viaduct on Saturday night.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and new-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—H. and G.—R. J. C.—E. S. and Co.—J. R. W.

VER DOYANT. (To Students only. The Secretaries of the R. I. B. A., and the A. A. will give all information respecting these Societies if written to at 9, Conduit-street, W.)—G. H. R. (The Silicate Solution, see advt. pages.)

MEMO. (Baldwin Latham's work on Sewerage, published by Messrs. Spon, is the most complete work we know of. There is also a small treatise on drainage, in Lockwood's series. The "Suggestions" published by the Local Government Board lately may be of help.)—C. F. W. (Numerous figures of the kind you send us occur in medieval masonry, but opinions differ as to their intention. Most probably it is a mason's mark.)

"BUILDING NEWS" DESIGNING CLUB.

LIST OF SUBJECTS.—1. A row of three shops for a village street, one being at the corner, suitable for the trades of a butcher, draper, and grocer. The houses to be three stories high, including the shop. A private entrance required to each. Frontage to corner shop, 20ft., others 18ft. each. Materials, brick and timber, and files for roof. Plans, elevation, and perspective sketch. Scale, 8ft. to the inch. 2. A pair of wrought-iron gates for a suburban villa, 8ft. wide, with stone piers. Scale 1in.

ELEVE. (We cannot entertain your suggestion of considering the ages of competitors. Such a task would be profitless.)—Y. Z. (The conditions of the Designing Club were published Sept. 29, 1878, in the BUILDING NEWS, a few copies of which are in print.)

DRAWINGS RECEIVED.—Maltese Cross, Con Amore, Memor Estor, T. G. Good, Essayez, Elève, East Anglian, Dunwich, Rusticus, J. C. in circle, T. W. P., Belteshazzar, James, Dagger and Triangle, Try, "Be to its Merits, &c." Pat, Ogmores, First Attempt, Signum, Burswell, Ubique, Norwich, Cymraeg, M. with leaves in circle, Omnia Vincit Labor, Melina, Pecksniff, J. G. in square and circle.

Correspondence.

A MEMBER OF A BUILDING COMMITTEE ACTING AS SURVEYOR AND CLERK OF WORKS.

SIR,—Not a few gentlemen would be glad to know your opinion, and a few other professional gentlemen's, how far a Building Committee has acted wisely and in the interest of the building and the subscribers, under the following circumstances. A public hall is being built by public subscription, from plans, &c., of a London architect of high standing, one of the oldest members of the R.I.B.A. The old public hall having been built about a dozen years ago proved defective and unsuitable, the builder of the same being a member of the present Committee, acting on their behalf during the competition of the contractors for the work, at the same time performing the duties of Surveyor, taking out the quantities for one of the competitors. The tenders were sent in and a few days after opened. The lowest estimate being from the oldest builder in the town, who has built a very nice church here to his credit under

Mr. Street, R.A., but he declined to do the work, the Committee having demanded of him stipulations beyond those in the specification; the next lowest being the builder for whom the Committee-gentleman has taken out the quantities, a man who has only lately taken to the building trade, his estimate being only £6 below the next, a thorough practical builder of many years' London experience. Since the commencement of the work, the said Committee-gentleman has been appointed to act as Clerk of the Works. The quantities have been proved not quite correct, and since the digging has been commenced other difficulties have crept up, which will have to be met by the usual bill of extras, &c., of course most of the subscribers thinking everything is being done with the knowledge and consent of their architect. I presume I am correct in thinking that a member of a public body acting in a similar way, would be acting illegally and rendering himself liable to a fine?—I am, &c.,
AN OLD READER.
10th March, 1879.

DISTRICT SURVEYOR'S FEES.

SIR,—Mr. Hugh Rounmieu Gough writes you respecting a Building Act case, decided lately by the magistrate, in which I claimed notice for works done by Messrs. Adams. You must permit me to say that I cannot accept Mr. Gough's account of the facts. The law is that Messrs. Adams shall give the District Surveyor notice of their work with "particulars." How is that officer to know otherwise what is being done, so as to be able to perform his duty? Mr. Gough knows very well that Messrs. Wontner Smith's notice was for nothing more than this (I give the exact words and the whole of them):—"Putting in new window and building for lift, &c." How can he pretend to tell your readers that this ought to afford to the District Surveyor the information, with "particulars," that Messrs. Adams were, not only *separately*, but *subsequently*, to take a contract for steam-piping and cooking apparatus? I may say that it was with considerable difficulty I discovered what Messrs. Adams were doing; and their work was very wrong indeed. Suppose the club-house had been burnt down through those steam-pipes; would the District Surveyor have been responsible for negligence under Messrs. Wontner Smith's notice for "a new window and a lift," because they put an "and" at the end of it?

As regards the fees, the case is plain enough. Each builder becomes liable for his own fee—generally a very trifling sum; and if there should be several thus incurred, the District Surveyor will, I believe, be always found ready to abate part. My own abatements are very substantial in such cases.

By the way, Mr. Gough forgets to tell you that I begged off "the penalty in each case of £20," wishing only to have the law settled—as it had frequently been before. Messrs. Adams were fined one shilling for not having given notice. As regards the penalty of £20 for having fixed the steam-pipes (systematically as a whole, and not "a steam-pipe" by accident) in dangerous proximity to the wood-work, it obviously ought to fall upon the architect under whose directions such a thing has been done, and unfortunately the Building Act cannot reach him. But if the fire insurance of the Army and Navy Club-house were pronounced invalid, on account of the cause of fire having been steam-pipes fixed contrary to law without the public surveyor's knowledge, how would Mr. Gough stand, and what would the lawyers' say to his shabby quibbles about the necessity for economising the little fees by which the District Surveyors are paid for their trouble and often serious responsibility. I hope Mr. Gough may one day be a District Surveyor himself, and then he will vote the other way to a certainty. If he should say that he has no ambition to hold such an office, my case is all the stronger.—I am, &c.,
ROBERT KEER.

A NATIONAL STYLE OF ARCHITECTURE.

SIR,—I was much struck with two letters in the Correspondence column of your issue of 28th February. They are in opposition, and show forcibly the dilemma in which architects are placed regarding the development of a new and suitable style of art.

In the one letter the writer bemoans the fact that we do not seem in an "honest state of transition or development." We copied Greek art, then Roman, till someone cried, "We ought to

throw aside pagan art and develop Christian art," i.e., Gothic. Then such men as the late Sir G. Scott came to the front, and we pass through an epoch of careful restoration of Mediaeval work. All praise to such careful restoration; but applied to modern requirements we pass through a fever of Gothic contortions—from Early Pointed to Late Depressed, with a jumble of everything from anywhere thrown in as a spice; till architecture becomes without a principle, degraded to a fashion, and we are told in a mincing manner that the latest fashion is the "Queen Anne."

The natural outcome of all this is illustrated in the other letter, where we are told that a fireplace being designed in the strictest "truth and consistency," i.e., large, square open jambs, with a dog-grate for wood fuel, puffs out black smoke most provokingly in the designer's face when he attempts to burn coals (probably) therein; but, miraculous to tell, it ceases when a glass smoke-board is put on.

When will it be known that architecture (or art) does not consist in copying ancient forms or ornament, nor in being Pagan or Christian; but in constructively meeting the requirements of the case, and in a tasteful manner.

Architects must copy, not *what* the ancients did, but *how* and *why* they did it. The mere copying what the ancients did and of conglomerating different parts, results only in the *want* of style.

Who is the successful designer of the present day? Not the architect, but the engineer. The one is a copying clerk to old forms, the other is a thinker, a designer, an applier of mechanical contrivances to meet present requirements, and, consequently, whatever he makes possesses style as distinctive of the 19th century as the Parthenon or the Baths of Caracalla are of the Athenian and Roman period. We have only to point to the beautiful arched roof of glass and iron of the railway station, the catenary curve of the suspension bridge, the lattice work of the girder-bridge, &c. Each possesses a new style intrinsically their own; and when touched by the wand of taste, after meeting constructive requirements, seem to me almost perfect and beautiful.—I am, &c.,
"19TH CENTURY."

FIREPLACES AND THEIR CONSTRUCTION.

SIR,—It may seem out of place to write about alterations in the form of fireplaces at this time of day, but I think that some little improvement may still be made on their construction. As the object of a fire is to heat the whole apartment, and not the wall against which it is placed, I think the chimney-piece might with advantage be made to project further into the room than is generally the case at present (something in the style of the fireplaces in old castles), so that the grate might be brought well forward into the apartment. There would then be an open space or chamber left behind the grate, into which the soot might drop. It seems to be an evident mistake that the part of the wall behind the fireplace should be made so much *thinner* than the other parts of the wall, as it usually is. This is especially the case in outside walls, where this part, instead of being thinner than the rest of the wall, should be made thicker to *retain* the heat from the fire, and not let it be spent on the outside of the wall altogether, and lost in warming the open air. Keeping the chimney-piece and grate well forward would to a considerable extent remedy this common defect, and it would at the same time enable designs for the prevention of the smoke nuisance being put into execution. For the furtherance of this other important object, I beg leave to submit a plan for consideration.

My proposal is, that in the top of the back of the grate—or, if that would not suit, in the top of a thin partition immediately behind the grate—there be made a round hole, from six to nine inches in diameter, and that into this opening there should be inserted a perforated iron cylinder, closed at one end (made either of light bar or perforated sheet iron), with the open end resting on the grate or partition, and the close end on an axle working in an eye attached to the back of the wall. The axis of the cylinder would be horizontal, and at right angles to the grate; and in the mouth of the chimney the smoke would pass through the cylinder, and a great part be retained in it in the shape of soot, so that part of the smoke would not go up the chimney at all. As the cylinder would soon get clogged,

I propose, for cleaning it, that two brushes of the same length as the cylinder be placed close to it, parallel to, and at the same distance from, the floor as the axis; and that there be a crank, with a handle, attached to the cylinder, to turn it round and bring it in contact with the brushes. The cylinder could be swept by turning the handle when the fire was cooled, or when necessary. Of course, the brushes would have to be cleaned (or even changed), and the chamber cleaned out occasionally. I think some method of this kind might be adopted to assist in mitigating the smoke nuisance in cities.—I am, &c.,
W. YOUNG BLACK.

COLOUR IN ARCHITECTURE.

SIR,—With reference to the paper on the above subject, read by Mr. J. W. Tonks, before the Birmingham Architectural Association, I think that in justice to the author it should be known that he is not in any way directly connected with the architectural profession, and further that Mr. Tonks does not profess to be an authority upon the subject which he treated.

Mr. Tonks is a "Designer," and as such is well-known in this town. Before commencing to read his paper, he told us that his opinions were simply those of an outsider, and that his only object was to give a few hints as to what, from an outsider's point of view, might be done to improve the appearance of our buildings, and that if we, as professionals, deemed them worthy of our consideration, our technical knowledge would suggest the proper means of carrying his ideas into practice.

With reference to what your correspondent says about the "Grand Hotel" and "School Board Offices," which by the way is altogether wide of the subject, permit me to quote the exact words used by Mr. Tonks. He said, "The use of terra-cotta of different colours is common among the modern buildings on the Continent, although but little adopted here. A mixture of it is seen in the new range of buildings in Colmore row, part of which is known as the 'Grand Hotel,' and another part as the 'School Board Offices.' The effect of a band of colour, though so moderately given, is good, and should encourage architects to seek by colour contrasts to balance, as far as may be, the neutralising effects of our climate, air, and smoke."

You will see, sir, that Mr. Tonks does not describe any building as the "School Board Offices," although I must confess that your abstract of his paper made it appear that he did so; but "A Birmingham Reader" ought to know that in brief abstracts such "slips of the pen" are almost unavoidable.

As to the introduction of terra-cotta in the Grand Hotel, Mr. Tonks was certainly at fault. The bands which he mistook for terra-cotta are in reality red stone; but the mistake was really not worth notice, as it did not affect his meaning in any way. It must be obvious to everyone, except "A Birmingham Reader," that what Mr. Tonks wished to point out was, not the use of any particular material, but the introduction of colour.—I am, &c.,
FRED. G. HUGHES.

Hon. Secretary of the Birmingham Architectural Association.

Queen's College, Birmingham,
March 11, 1879.

EXTORTIONATE CHARGES.

SIR,—There is not that difference in the scales of charges of the two journals referred to by "M." on p. 264, which would appear at first; but the extortion is none the less apparent. It is managed by what printers call "making lines." Let "M." pick out a longish "contract" advertisement appearing in the current issues of both journals and *count the lines*. He will find that the same advertisement is bumped out to make three or four more lines in one paper than the other, and charged accordingly. I invariably found this the case with advertisements sent on behalf of my Authority, and I pointed it out some time since to the Clerk; since then our advertisements have appeared only in your columns, and we always get as many replies as before.—I am, &c.,
A SURVEYOR.
March 8, 1879.

It is proposed to erect a stained window in the Lady chapel of the collegiate church of Crediton, Devon, as a memorial of the late Mr. Richard J. King, the well-known archaeological writer and the author of Murray's "English Cathedrals." Mr. King, who was formerly a magistrate for Devonshire, resided of late years in a cottage at Crediton.

Intercommunication.

QUESTIONS.

[5701].—**Sewerage.**—Would some of your readers kindly inform me at what inclination in a line of drainage it becomes necessary to have a tumbling bay, and, supposing a considerable length of sewer, would it be advisable to have flaps at each manhole to prevent the sewer gases rising to the highest point, and would this apply to a continuous sewer, as well as one that was stopped?—J. S.

[5702].—**Sanitary Examination.**—I believe that there exists some society holding examinations into the qualifications of sanitary engineers and inspectors, who award certificates of competency to the successful candidate. I should be much obliged to any correspondent who would give me the necessary particulars as to the mode, time, and location, fees, &c., or information as to where I could obtain it for myself. A list also of the books that had best be read on the subjects of the examination would also be thankfully received by—GOLUMPTIONS.

[5703].—**Stone Floors.**—I would like to know the cost of executing a stone floor of 22ft. bearings, supported by rolled iron girders, compared with a similar floor, carried out entirely with wood? I shall be obliged by your reader kindly informing me of the way to calculate the weight stone floors, composed of iron girders and 2-inch planks doubled (Lancashire system) will carry. Also, the best kinds of floors for stores and warehouses.—PECK-SNIFF.

[5704].—**Excursion.**—Will some reader give a list of any objects of architectural and archaeological interest between Rugby and Bedford, via Northampton, which would repay a visit by—BICYCLIST.

[5705].—**Chequered Plates.**—I should be obliged to any reader who would give me a description of chequered plates.—A YOUNG FETTER.

[5706].—**Labourers' Cottage Fittings.**—Would some of your readers give experiences connected with following items in labourers' cottages? 1st. In the kitchen or living room, is a range preferable to a good barred grate for a class that cannot afford meat to roast often in the twelve months, and that probably understands baking their cake on a flat griddle better than in a close oven? What small ranges, of value not exceeding £3, and of strong castings, have proved themselves good by some years' trial?—AGRICOLA, Cork.

[5707].—**Haslingden Flags.**—In looking over a specification of some property in the neighbourhood of Manchester, I find the following:—"Scullery, kitchen, and pantry to be flagged with 3-inch best Haslingden flags, and the stables and yards paved with 6-inch stackstead setts." Can any correspondent say where to get, and what is the quality of, the stone quoted? Is it as good as York stone?—M. WATSON.

[5708].—**Hospital Planning.**—I shall be obliged if some correspondent will inform me what is meant by the blocks of Hospital wards being arranged "en echelon."—S. P. G. T.

REPLIES.

[5692].—**Cast of Carving.**—Looking back at my original reply, under the above heading, Jan. 31st, I said, speaking passingly of modelling clay, that it was "procured in large quantities in Devon, principally in the neighbourhood of Chudleigh." "J. B." takes exception to this, saying the "statement is calculated to mislead." Is it so? A glance at the map of Devon will show the county to be some seventy odd miles across from east to west; and about the same in measurement from north to south. Now, if the compass be put on to the paper at Chudleigh-road station, and a circle struck at a radius of four miles, it will be found the line will embrace every one of the six parishes that "J. B." in particularising mentions as those the clay is dug from. Thus, it will be seen, I not only gave the county, but the locality where clay is procured, and, "J. B." instead of correcting, as he calls it, any error of mine, has merely added, as a matter of detail, the names of some half-dozen little parishes, all clustered together, wherein the clay is dug. I have been accustomed to use modelling clay almost daily for the last 20 or 30 years, and the result of my experience is given when I say that I have found the clay from the pits of Messrs. Watts, Blake, Bearn and Co., and of Messrs. Whiteway and Co., to be the best I ever used. "J. B.'s" knowledge of the yearly expenses of various clay merchants who ship, a knowledge so intimate that he is able to render an account of their annual disbursements to the penny, suggests that he is not altogether a disinterested person in the fluctuations of the clay market. Hence, what he says thereon necessarily bears less weight than it would do otherwise. But, it would be instructive if, instead of restricting his remarks to quibbles upon pipeclay, "J. B." would, taking a model from the excellent example of my old friend, Mr. H. Terry (Feb. 7th, '79), give further advice upon what he entirely ignores, the primary question asked, i.e., "Which is the best way to take casts of carvings?"—HARRY JIKES.
